ROYAL LONDON OPHTHALMIC HOSPITAL GUILD (MOORFIELDS EYE HOSPITAL) —The fifth annual general meeting of the Royal London Ophthalmic Hospital Guild (Moorfields Eye Hospital) was held on Jan 23rd at 20 Portland place W by *kind permission of Lady Samuel* Sir Marcus Samuel presided supported by Mrs Lang head of the Guild, Lady Agnes Frank, Lady Russell Reynolds Lady Maurice, the Lady Mayoress Mr H P Sturgis (chairman of the hospital) Mr A Gordon Pollock, Sir James Reid, and a large number of members and friends The report stated that H R H Princess Christian of Schleswig Holstein had graciously consented to become president of the guild The guild founded to assist the hospital, which had to contend with lack of funds and public interest had been able to aid with blankets coverlets and sheets for the beds, and for the past two years to maintain a cot and woman's bed in the wards The nurses library had been replenished and members had rendered personal service by visiting the patients An interesting event was the centenary dinner when the collection at the ' Guild table amounted to £136 special thanks being due to Mrs Lang for the trouble which she took in the matter The country centres were growing in importance and two new ones had been added—at Bury St Edmunds and Pinner The members now numbered 200 with 100 associates 50 having joined during the year and only three had resigned On the motion of Lady Reynolds the report was adopted Mr Sturgis, on the part of the hospital, expressed the gratitude of the committee [illegible] ery penny subscribed [illegible] ner Mr Pollock also [illegible] the guild and its aid to the centenary fund which he hoped would eventually pay the rent and taxes The officers and council were re elected and a vote of thanks to Sir Marcus Samuel and Lady Samuel closed the proceedings

THE LADIES' HEALTH SOCIETY, MANCHESTER —This society held its annual meeting on Jan 13th at the Manchester town hall The report showed that its work extends over certain of the poorer parts of Manchester and Salford which are divided into 23 districts, in each of which lives an intelligent woman belonging to the working class called a health visitor paid by the society and supervised by ladies who give of their time and energies in helping their poorer sisters The society is assisted by the corporations of Manchester and Salford which pay the salaries of nine and of four visitors respectively Dr J Niven gives his valuable cooperation The visitors go to the dwellings in their districts and where disease breaks out they show how [illegible]

adoption of the report, spoke in high praise of the society s usefulness Its work is done among the poorest and if we are to have ' a strong and better population in the future we must begin with the rising generation As to the poor mothers themselves they had to go early to their work and had no chance of learning household duties or the bringing up of children ' But mothers ought not to be so ignorant and helpless or obliged to work so near their confinement or so soon after it We may learn something from Germany and from the Jews as to these matters Dr Niven, in seconding a vote of thanks to the Lord Mayor, said that he had been coming to the conclusion that ' a great many of the babies who died from summer diarrhœa died from starvation' , that the mothers did not know what food to give them and had not enough "Many poor mothers could not suckle their children because for lack of proper nourishment they were in a state of physical misery' This is a pitiful statement to have to make "Pity 'tis, 'tis true '

Births, Marriages, and Deaths.

BIRTHS.

Bryant.—On Jan. 17th, at Mansfield-street, Cavendish-square, W., the wife of J. H. Bryant, M.D., F.R.C.P., of a son and a daughter.

Ennion.—On Jan. 16th, at Meldreth, Royston, Herts, the wife of O. R. Ennion, M.R.C.S., L.R.C.P., of a daughter.

Gordon-Green.—On Jan. 23rd, at Westerton, 46, Beach-road, Southsea, Hants, the wife of Staff-Surgeon H. W. Gordon-Green, R.N., M.R.C.S. Eng., L.R.C.P. Lond., of a son.

Passmore.—On Jan. 20th, at Felbrig, Carshalton, Surrey, the wife of William Henry Passmore, M.R.C.S., L.R.C.P. Lond., of a son.

Payne.—On Jan. 19th, at Brunswick House, Cumberland Gate, Kew, the wife of Mr. E. L. Payne, M.R.C.S., L.R.C.P., L.S.A., of a daughter.

Roche.—On Jan. 18th, at Rochester, the wife of Lieutenant Colonel E. A. Roche, R.A.M.C., of a son.

Wilson.—On the 20th instant, at Denham House, Goldhawk-road, W., the wife of James Wilson, M.D., of a daughter (prematurely).

MARRIAGE.

Brockwell—Smith.—On Jan. 18th, 1905, at Christ Church, Gipsy-hill, by the Rev. R. C. Joynt, John Brocas Chambers Brockwell, M.R.C.S. and L.R.C.P., eldest son of the late Dr. John Brockwell, of Gipsy-hill, S.E., to Annie Amelia, elder daughter of the late William Edwin Smith, of Lewes, Sussex.

DEATHS.

Beaumont.—On Jan. 22nd, at the Middlesex Hospital, London, W., Edward Frederic Beaumont, M.B., of Bardwell-road, Oxford, aged 28.

Birmingham.—Jan. 23rd, in Dublin, Ambrose Birmingham, M.D., Professor of Anatomy, Catholic University of Ireland, aged 40 years. R.I.P.

Mouncey.—At Earlestown, Lancashire, on the 21st inst., Louisa Elizabeth Ainley Mouncey, eldest daughter of Chas. J. Mouncey, M.B., and Mrs. Mouncey, aged 19 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE CORONER, THE MEDICAL MAN, AND THE JURYMEN

A SINGULAR discussion took place at the Lambeth coroners court on Jan 23rd Mr John Troutbeck the coroner, was holding an inquiry regarding the death of a child, aged two months, who had been suffocated whilst in bed with its parents Evidence was given by a medical man who had been sent for when the death was discovered, and Dr Ludwig Freyberger was summoned to describe the cause of death At this point a juryman said "I should like to ask why a second doctor was called in To this the coroner replied "Because I chose The juryman now expressed the opinion that the course taken "was most unfair, and was in return promptly informed by the coroner: "It has nothing to do with you Sir" The foreman of the jury here interposed with a remark which according to the published reports, seems not to have advanced beyond the opening words when the coroner abruptly refused to allow any discussion on "a question of general policy The foreman however, persevered and eventually succeeded in saying "I think the doctors who devote their lives to the service of the people should be called When addressing the jury in his summing up the published accounts of the incident describe the coroner as saying "This is a question of a case which requires special skill and that is not possessed by all general medical practitioners It would be just as well to say that all doctors possessed special skill in surgery and many other things If is not a question of ordinary but of special skill and evidence

Without commenting on the circumstances of this individual case we may express the opinion that no exceptional pathological skill is required for the examination of a case of asphyxia The calling of special witnesses to give evidence of a purely pathological nature is a subject which requires very careful consideration and has already been discussed at great length in the columns of THE LANCET

THE ACTION OF ANÆSTHETICS ON PLANTS

To the Editors of THE LANCET

SIRS —I recently made an experiment with a plant here which I desire to bring under your notice The plant in question, which I have planted in a pot, is popularly known here as sensitive grass It is "mimosa pudica" On touching the leaf at any point with the finger it immediately closes up This is generally known of course I find however, that on exposing it to the vapour of ammonia or formalin it immediately closes, but stranger still is the fact that it is susceptible to anæsthesia If exposed to chloroform held closely (but not in contact with it) the leaf remains open and shows no response, as in the case of ammonia or formalin, but if after one and a half or two minutes the chloroform is withdrawn the *open* leaf seems quite impervious and oblivious of any stimulus such as contact with the finger or exposure to ammonia or formalin I do not know whether the anæsthesia of plant life is known, so venture to place the information before you

I am, Sirs, yours faithfully,

Brisbane Australia, Nov 26th, 1904 R MACDONALD

*** Our correspondent will find an annotation on the subject in THE LANCET of Jan 9th 1904 p 108

AN UNFORTUNATE DEPARTURE

THE picture post card is now being much used by public institutions and those interested in the prosperity of certain seaside towns and health resorts as frank advertisements This makes the issue by a medical man of a post-card displaying his house beneath which in bold type is the legend "Dr A——s an unfortunate departure The specimen which has been sent to us is one we are informed, "of numerous copies that have been going the rounds through the post here,' and would certainly serve to instruct the public where the medical man in question could be found The mischief of the card entirely depends on what is implied in "going the rounds" If the cards have been sent only to Dr A——s patients no harm has been done but if there has been anything like a broadcast distribution of them the medical man in question has erred

THE CLIMATE OF MANILA.

To the Editors of THE LANCET

SIRS —I should be glad if any of your readers would kindly give me any information in the correspondence columns of THE LANCET as to the climate of Manila and its suitability as a residence for one troubled with chronic bronchitis I am, Sirs yours faithfully,

Jan 21st, 1905 H

THE "NORMYL CURE

A CORRESPONDENT has forwarded to us some literature dealing with the treatment for intemperance which goes under the name of the "Normyl Cure' Its usefulness is apparently vouched for by the Rev Hugh B Chapman, vicar of St Luke's Camberwell Our correspondent seeing that a technical description would be furnished to any medical man wrote for the same, and when he had received it forwarded it to us From this we learn that the chief constituent of "Normyl" is prepared from a member of the group of plants known as 'the aristolochia' combined with sundry other nerve tonics and sedatives While not denying that drug treatment has its uses in restoring to health those who are intemperate—atropine, for instance, has we believe, been used with success—we rather doubt the wisdom of anyone, however honest and well meaning he may be, giving testimonials as to the "cure of drunkenness The best thing for the proprietor of the "Normyl cure to do would be to submit it to the Government inspector of inebriate homes who would, we doubt not, be enabled to make an extensive trial of the same under the very best scientific safeguards

LADY HOSPITAL MANAGERS

To the Editors of THE LANCET

SIRS —The Royal Portsmouth Hospital may be added to the list named by your correspondent, in which ladies act on the committee of management We have four in a total of 36 members The addition was made some years ago with a certain amount of fear and trembling on the part of some members of the committee but the change has worked well There are many matters associated with household management and domestic thrift in which the advice and judgment of a lady are most valuable

am, Sirs yours faithfully,

Southsea Jan 22nd, 1905 HENRY RUNDLE

THE CASE OF DR A D GRIFFITHS

To the Editors of THE LANCET

				Mr T Garrett Horder	0	10	6

I am, Sirs, yours faithfully,

23, The Walk, Cardiff, Jan 23rd, 1905 ALEX P FIDDIAN

IS LEPROSY CURABLE?

TREATMENT

I M S, is

to Lepers

society supports 600 lepers) three cases are declared by the deputy sanitary commissioner of the district to be "to all intents and purposes completely cured Others show less favourable results The hopeful cases will be isolated and observed for six months before a final decision can be pronounced If found to be of lasting benefit the society will adopt the treatment in others of its 42 asylums in India and the East

A WARNING

To the Editors of THE LANCET

SIRS —It cannot be too widely known that a youngish fair, foreign looking man about 5 feet 4 inches without hair on his face is visiting the houses of medical men in the South Kensington district about a quarter past eight in the morning with a bogus message ' to go directly and whilst it is being delivered upstairs makes off with the coats available I am Sirs yours faithfully,

Jan 11th 1905 G P

THE FEES OF MEDICAL WITNESSES

To the Editors of THE LANCET

SIRS —Last week I had to give evidence at the quarterly sessions in a case of wounding Before the case came on I was asked to give a receipt for my fees and noticed that 13*s* was allowed for expenses I was not paid at the time but the money was sent afterwards with a deduction of 10*s* and a message that a mistake had been made and that only 3*s* could be allowed for expenses The distance from home was 11 miles and I was detained all day, so that I had to get lunch The 3*s* barely covers the train fare

I am, Sirs yours faithfully,

Jan 23rd, 1905 M D

*** By the Order of the Home Office 'reasonable travelling expenses may be paid where the witness has to travel more than two miles to give evidence What may be considered reasonable is practically in the discretion of the officials —ED L.

IMPROVEMENTS IN THE TECHNIQUE OF VACCINATION

To the Editors of THE LANCET

SIRS —There are at present two methods in use for ejecting the vaccine from the usual vaccine tube In both the two ends of the tube are broken off, then in the first method the operator blows out the vaccine with his mouth, in the second he uses a small rubber cap The first is dangerous and the second is cumbersome A better plan is to remove only one end of the tube preferably that which contains least air, and to warm the other (closed) end with a lighted vesta The whole of the vaccine may in this way be ejected directly into scarifications or if preferred on to a lancet or watch-glass. All risk of sterilising the vaccine is avoided by holding the tube in the left hand while the match is held in the right. Both from the points of view of asepsis and of convenience the method seems to have distinct advantages.

I am, Sirs, yours faithfully,

London Hospital, Jan. 19th, 1905. H. S. SOUTTAR.

YANATAS.

To the Editors of THE LANCET.

SIRS,—*Apropos* of remedies for seasickness there is a remedy named "Yanatas" sold by the Yanatas Company, Limited, 1, Granville House, Arundel-street, Strand, W.C. Will you kindly inform me what is the composition of this liquid (orange coloured and of a narcotic odour) and also whether in your opinion it would be safe to administer it continuously for the cure of insomnia? This question is of public importance, since Yanatas is recommended as a cure for "sleeplessness and all disorders of the nervous system."

I am, Sirs, yours faithfully,

Cobham, Jan. 23rd, 1905. J. L. W. KITCHING.

⁂ We do not know the composition of the liquid referred to but shall be pleased to submit a sample forwarded by our correspondent to analysis.—ED. L.

THE LANCET IN 1846.

A CORRESPONDENT sends us the following interesting extract from "The Newspaper Press Directory for the Year 1846, published by C. Mitchell at his Town and Country Advertising Office, Red Lion Court, Fleet Street, London":—

LANCET.

Saturday. Price 8d. Established October 1, 1823.

ADVOCACY. Medical and Chemical Sciences—Politics—Liberal—Anti-Poor-Law. This periodical is well known to be conducted with great ability by Mr. Wakley, M.P., the Coroner; and though, of course, principally devoted to medical topics, the active reforming spirit of its Editor imbues it with more of what may be called an *aggressive* character; and induces on its part a more severe sort of censorship over the authorities, than may be observed in its powerful professional rival. In particular, it exhibits all his uncompromising hostility to the new Poor-law. And the close connexion of the science and practice of medicine with many important departments of jurisprudence and of law (as on the bastardy clauses of the Poor-law, the medical attendance on unions, sanitary regulations, [illegible] for animadversion and attack on [illegible] order of things. This journal is thus brought into closest connexion, or rather collision, with the Poor-law authorities throughout the country; and the incessant avocations of its editor, whether as Senator or Coroner, supply constant incentives to exertion and continual stimulations to attack, on some subject or other. Published by John Churchill, 46, Princes Street, Soho.

The following is the wording of the title-page of THE LANCET in 1846:—

THE LANCET. A Journal of British and Foreign Medical and Chemical Science, Criticism, Literature and News. MDCCCXLVI. In Two Volumes Annually. Volume I.' Edited by Thomas Wakley, Surgeon, M.P. for the Metropolitan District of Finsbury, and Coroner for the County of Middlesex. London: Printed for the Editor, and published by John Churchill, Princes Street, Soho.

The page was very nearly as large as that of to-day and the column was of the same size—viz., three inches by nine inches—with two columns to the page. The first week's number of the year consisted of 28 pages and the last number of the year 24 pages. The index consisted of 14 pages for Volume I. and 10 pages for Volume II. and there was no separate list in the index of the illustrations. The total number of pages in Volume I. amounted to 726 and in Volume II. to 714, or a total for the year of 1430, whereas for the first half year alone of 1904 the total number of pages, including the index, amounted to 1882. Although the extract quoted above states that THE LANCET was established on Oct. 1st, 1823, as a matter of fact the first issue was dated Sunday, Oct. 5th, 1823, and was published by G. L. Hutchinson at THE LANCET Office, 210, Strand, where all communications for the Editor were "requested to be addressed (post paid)."

THE CHOICE OF AN ANÆSTHETIC.

To the Editors of THE LANCET.

SIRS,—In reply to "Hector" in THE LANCET of Jan. 21st, having had a varied experience in the administration of all kinds of anæsthetics in villages in remote parts and also in hospitals and in private in the west end of London, I venture to advise "Hector" as follows: Use ether as your anæsthetic and for children in a Rendle's mask, for adults a "Clover." Do not use a "Junker" for chloroform, it will only prove a success in the hands of those who are almost daily using it. I advise ether on account of its safety over other anæsthetics.

I am, Sirs, yours faithfully,

Chichester, Jan. 23rd, 1905. A. M. BARFORD.

◆

Jack.—Influenza must by treated as is any other specific fever—i.e., the patient must rest in bed and the diet must be light.

E. L. P.—We have not examined the preparation but we will do so if our correspondent will forward us samples.

Irish Reader.—We should have nothing to do with the apparatus in question.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

SATURDAY (4th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

WEDNESDAY (1st).—OBSTETRICAL SOCIETY OF LONDON (20, Hanover-square, W.).—8 P.M. Annual Meeting. Specimens will be shown by Mr. Targett, Mr. Handley, Dr. F. E. Taylor, and Mr. Bland-Sutton. Short Communication:—Dr. E. W. H. Groves: A New Operation for the Cure of Vaginal Cystocele. The President (Dr. Malins): Annual Address.

THURSDAY (2nd).—RÖNTGEN SOCIETY (20, Hanover-square, W.).—8.15 P.M. Messrs. Newton and Son will show Dr. T. Holland's X Ray Diaphragm Compressor. Paper:—Dr. C. A. Wright: Some Points in the Construction of a High Frequency Machine (accompanied probably by some novel exhibits).

NORTH-EAST LONDON CLINICAL SOCIETY (Tottenham Hospital, N.).—4 P.M. Clinical Cases.

FRIDAY (3rd).—SOCIET[illegible] Hanover-square, W.).—8.30 P.M. Ex[illegible] rs before and after the meeting. [illegible] nce of Ethyl Chloride in Commerc[illegible] hyl Chloride in Eye Practice, with [illegible] Barton: Continuous Administrati[illegible] ns about the Upper Air Passages [illegible] enced by Dr. McCardie).

WEST KENT MEDICO-CHIRURGICAL SOCIETY (Royal Kent Dispensary, Greenwich-road, S.E.). 8.45 P.M. Paper:—Dr. Annis: Immunity against Disease.

LARYNGOLOGICAL SOCIETY OF LONDON (20, Hanover-square, W.).—5 P.M. Cases and Specimens will be shown by Mr. C. A. Parker, Dr. F. Spicer, Mr. P. de Santi, and others.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (30th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. J. M. H. Macleod: Clinique. (Skin.) 5.15 P.M. Dr. H. Tilley: Nasal Catarrh, its Causes, Diagnosis, and Treatment.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr. Saunders: Congenital Syphilis and its Treatment, with cases.

TUESDAY (31st).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies street, W.C.).—4 P.M. Dr. W. Ewart: Clinique. (Medical.) 5.15 P.M. Mr. H. B. Robinson: On Diseases of Ducts of the Breast.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr. M. Moullin: Anterior Displacement and Stenosis.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.).—4.30 P.M. Lecture:—Mr. H. W. Carson: Diseases of the Naso-pharynx.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen-square, Bloomsbury, W.C.).—3 30 P.M. Dr. Batten: Polioencephalitis, its Relation to Poliomyelitis.

WEDNESDAY [illegible] GRADUATES' COLLEGE AND POLY- [illegible]).—4 P.M. Mr. P. G. Freyer: [illegible] Mr. A. W. M. Robson: Pancreatic [illegible]

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr. Beddard: Practical Medicine.

CENTRAL LONDON THROAT AND EAR HOSPITAL (Gray's Inn road, W.C.).—5 P.M. Demonstration:—Mr. S. Low: Oro- and Laryngo-pharynx.

THURSDAY (2nd).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. Hutchinson: Clinique. (Surgical.) 5.15 P.M. Dr. T. W. Eden: Acute Torsion of the Pedicle in Pelvic Tumours.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr. Davis: Cardiac Disease: Treatment.

CHARING CROSS HOSPITAL.—4 P.M. Mr. Waterhouse: Demonstration of Surgical Cases. (Post-Graduate Course.)

MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (7, Fitzroy-square, W.).—5 P.M. Lecture: Dr. J. E. Squire: "Murmurs" not dependent on Diseases of the Heart. (Post-Graduate Course.)

SAMARITAN FREE HOSPITAL FOR WOMEN (Marylebone-road, N.W.)—3 P.M. Dr. McCann: The Treatment of Pruritus and Allied Conditions.

THE HOSPITAL FOR SICK CHILDREN (Gt. Ormond street, W.C.).—4 P.M. Lecture:—Mr. Parsons: Glioma of the Retina.

FRIDAY (3rd).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. R. Lake: Clinique. (Ear).

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith road, W.).—5 P.M. Mr. Bidwell: Surgical Treatment of Chronic Gastritis.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen-square, Bloomsbury, W.C.).—3 30 P.M. Dr. Batten: Nerve Terminations in Muscle.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. II. of 1904, which was completed with the issue of Dec. 31st, and the Title-page to the Volume, were given in THE LANCET of Jan. 7th.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1904 are now ready. Bound in cloth, gilt lettered, price 18*s*. carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s*., by post 2*s*. 3*d*.

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

METEOROLOGICAL READINGS.

During the week marked copies of the following newspapers have been received:—*Westminster Gazette, Surrey Advertiser, Reading Mercury, Mining Journal, Local Government Chronicle, Daily News, Liverpool Post and Mercury, Daily Chronicle, Standard, Literary Digest, Aberdeen Weekly Free Press, Plymouth Mercury, Freeman's Journal, Hertfordshire Mercury, Windsor and Eton Express, Liverpool Courier, Eastbourne Chronicle, Morning Leader, St. James's Gazette, Manchester Evening News, Newcastle Daily Chronicle, Newcastle Journal, Bath Weekly Argus, &c.*

in the chest, a fact which emphasises the importance of preventing chills after release from isolation and of dispensing with the hot bath immediately before discharge. But I should regard it as unlikely that in the convalescent stage there is much danger of distribution by talking of those pathogenic organisms the habitat of which is the throat. Any fluid which may be sprayed in the act of talking comes from the neighbourhood of the incisor teeth and as there is a constant flow of saliva backwards to the pharynx it must be only occasionally that in this stage such fluid contains bacteria derived from the fauces.

The nose.—Rhinitis is a common and very important complication. The great facility this affection offers in young children for a widespread diffusion of infection when the discharge contains the infective agent is sufficiently apparent. It is often most intractable to treatment and the knowledge that it is frequently associated with "return" cases leads to its being the main cause of prolonged detention of patients in hospital. Every endeavour is made that a patient shall leave free from nasal affection, though there can be no doubt that the condition often relapses within a short time of the child reaching home. It not infrequently is first noticed after the patient has been discharged. At Birmingham, while only 6 per cent. of all cases had an abnormal condition of the nose at the time of discharge, no fewer than 22 9 per cent. of the infecting cases had been noted as leaving with such abnormality. Dr. Knyvett Gordon relates that rhinorrhœa was associated with 39 out of the 174 alleged infecting cases which occurred in Manchester in the years 1902 and 1903; in eight cases it had been present at the time of leaving hospital; in 31 it appeared later. Professor Simpson found that of 90 discharged patients whom he regarded as probably the cause of fresh outbreaks 49 had nasal discharge, five had sore nose, and 15 had cold in the head with running at the nose. But it must be noticed that rhinorrhœa does not necessarily prove infectious in the family. It may be calculated from the Birmingham statistics that less than one-eighth of the cases discharged with a morbid condition of the nose became associated with the "return" cases. This may be due to one of the following causes: the exposed children may not be susceptible; the discharge may never actually be conveyed to them; or the discharge may not in all cases carry with it the infecting virus. It is probable that the last is most frequently the correct explanation, for in diphtheria the rhinorrhœa which sometimes occurs in convalescence is often found not to be associated with the presence of the Klebs-Löffler bacillus. In other words, the risk attached to rhinorrhœa would appear to be that if the infecting agent is still present on the mucous membrane of the nose the discharge will act as a vehicle for its distribution. From many observations it seems likely that in both scarlet fever and diphtheria persons may be released from isolation still carrying the contagium on their mucous membranes and yet prove harmless unless catarrh is set up and the resulting discharges act as carriers of infection.

The ears.—Otitis is also a common complication of scarlet fever. Among nearly 11,000 patients treated in the Board's hospitals during 1903, 15 per cent. suffered while in hospital from otorrhœa. Even this does not include all, for not rarely it occurs for the first time after the patient has left hospital. Otorrhœa which has ceased for weeks is apt to recur when the child comes again under home conditions. The frequency of this complication being admitted, what is its potentiality for transmitting infection? Dr. Millard states that otorrhœa was present on discharge in 2·2 per cent. of alleged infecting cases as compared with 1·5 per cent. of all cases. The inquiry is to some extent obscured by the fact that rhinitis often co-exists with the otitis (*vide* Professor Simpson's table), and the difference is not sufficiently great to enable one to say that otorrhœa plays a very important part in the causation of "return" cases. Since otorrhœa, for anatomical and pathological reasons, frequently persists for a long time after the original infective process with which it was associated has disappeared this observation is of considerable interest. It may be debated whether the fact that otorrhœa is less infectious than rhinorrhœa results from the specific contagium being frequently wanting in the secretion or because with ordinary precautions there is less risk of the discharge being brought in contact with the mucous membranes of other children.

Desquamation.—Against the infectiousness of secondary peeling and late desquamation of the feet there has been accumulated a considerable amount of evidence; for example, at Birmingham during 1896–98 while 8·2 per cent. of all patients left with some late peeling of the feet only 7 per cent. of alleged infecting cases had exhibited this condition on discharge. The impression that even earlier desquamation is not infectious has been gaining ground for several years but definite information on this point is not yet very extensive. In 1895 Dr. Boobbyer[6] stated that his experience as medical officer of health led him to believe that too much importance had been attached to risk of infection from desquamation. He pointed out that the disease frequently failed to spread from an actively desquamating patient (though surrounded by susceptible persons) if the mucous surfaces had been only slightly invaded. Dr. H. Meredith Richards,[7] then superintendent of the Birmingham Fever Hospital, also expressed the opinion that desquamation was simply concomitant and not the essential cause of infection. Dr. E. G. Gilbert[8] of Tunbridge Wells remarked that for 20 years he had acted with success on the conviction that in a desquamating skin after scarlet fever there was no danger to others and that if the throat and the nose were quite sound isolation of the patient was not necessary for more than a month. Dr. J. Priestley[9] in the same year recorded that at Leicester, at the time of an outbreak of small-pox, about 120 children in various stages of desquamation after scarlet fever were sent to their homes and no secondary cases occurred at any of these houses. In 1902 Dr. Millard[10] of the Leicester Fever Hospital reported that he had adopted four weeks as the minimum period of isolation and had discharged during three months 190 patients after an average period of detention of 35·3 days. The exact number was not given but it was stated that many of these were still desquamating. Of the five cases which had gave rise to fresh outbreaks in their own homes only one had been noted as having desquamation present on discharge and in this patient the peeling was confined to the feet and the nose was found to be unhealthy. From several of the Board's hospitals during the past two or three years a number of patients who had not suffered from complication have been discharged desquamating at the end of four weeks' detention but no statistics as to results have yet been published. At Southampton during 1903 Mr. R. E. Lauder[11] also put the matter to the test and ignored desquamation as a reason for further isolation. He reports that 325 convalescents left hospital during the year. Of these, 204 patients who had not suffered from complications during their stay in hospital were discharged peeling, after an average detention of 28 days; there were only two "return" cases. 33 were discharged without desquamation or complication after an average stay of 33 days; there were no "return" cases. The remaining 88 patients, in whom complications of various kinds had occurred, left after an average stay of 50 days and there were five "return" cases. Mr. Lauder remarks: "If peeling *per se* were infectious then it is almost impossible to conceive how 204 patients discharged from the hospital in a peeling condition failed to be responsible for more than two return cases."

No morbid condition.—It is not uncommon for patients discharged apparently free from all abnormality to give rise to "return" cases. Dr. Boobbyer stated that 11 out of 29 infecting cases which were discharged from the Nottingham borough hospital in 1893 were normal on discharge. Dr. Millard recorded that 58 per cent. of the infecting cases at Birmingham were quite clear in every way at the time of leaving hospital. It must be recognised, however, as I have already related, that a morbid condition not infrequently develops or recurs after the child has been sent home and that this is apt to be followed by the occurrence of "return" cases.

Conclusions.—To sum up the results of these investigations, the evidence that infectivity lies not in the desquamating cuticle but in the throat and nasal cavities is decidedly strong. In scarlet fever, therefore, as in diphtheria, it must be impossible to ascertain definitely by clinical means when the patient has been freed from infection. It must not be assumed, however, that prolonged infectivity is the rule; it is probable that the majority of patients are free from infection at the end of the minimum periods of isolation usually prescribed—the six weeks for scarlet fever and the four weeks for diphtheria *It would seem impossible to* discover by clinical means the minority who retain infection longer and difficult even to differentiate those by whom transmission of infection is likely The impression derived from experience has been that such transmission is especially liable to occur from those who suffer from rhinitis at the time of their discharge or have suffered from this complication during their period of isolation, and this impression has been supported by statistics whenever subjected to that test A nasal discharge, therefore, while not to be regarded as proof that the patient continues infectious is a symptom to be viewed with considerable suspicion, for if the contagium is still resident in the mucous membrane of the nose it will unfailingly act as a vehicle for its distribution

Review of suggested methods of indirect infection —Having acquired from the study of the convalescent more or less definite ideas regarding the infectivity of scarlet fever one is now in a position to consider critically the various ways which have been suggested for indirectly acquiring the disease

Milk —I shall deal very briefly with milk as a vehicle of infection Several outbreaks[12] of scarlet fever have been proved to the satisfaction of the medical officers concerned to be *due to the consumption of contaminated milk It is* possible that this occurs more frequently than is known, for the milk supplied in towns often comes from various sources, passes through several hands and suffers much blending before it reaches the consumer, and it is thus difficult to trace the career of any given sample

Unrecognised cases —I next come to the influence of unrecognised cases which there is reason to believe is one of the chief causes of the failure of isolation to eradicate the disease It is now widely appreciated that scarlet fever, like diphtheria may exist in an extremely mild form, so mild that a considerable number of cases do not come under medical observation at all and so are never isolated There are patients also with marked throat affection in whom the rash either does not occur or has such a brief existence as to escape notice It is not at all unusual for such cases to be admitted into hospital under certificate of diphtheria Cultures prove negative and desquamation suggestive of scarlet fever ensues in spite of the fact that no rash has *been observed before or after admission*

Scarlatinal sore throat —Again it is within the experience of everyone that inflammation of the throat is apt to arise in households in which scarlet fever has been notified and I think we are justified in considering it probable that many of these cases are scarlatinal in nature Murchison wrote many years ago 'I have frequently found that when one or two children in a house have had scarlatina every adult in the same dwelling has suffered from a severe angina' In cases of this kind which have come under my observation, although the throat affection has been severe no rash has been observed nor has desquamation followed

Healthy infection-carriers —The part played by the health next under consideration The it is known, may exist in th who have been intimately exposed to infection and in a variety of circumstances it is believed may be communicated to others who develop the disease It is possible that in scarlet fever healthy persons may similarly carry the infective agent in their throats but in the absence of bacteriological evidence this must remain uncertain Even in diphtheria we have no means of estimating the magnitude of the part the bacillus carrier takes in the spread of infection I may mention however that it is very rarely that one hears of either disease occurring in the homes of any of the staff of a fever hospital or among their friends This is in spite of the fact that 10 per c
while on duty in
Hospital have be
throats

Temporary immunity —This incidentally leads me to raise rather an interesting point Nurses and medical officers not infrequently do not develop scarlet fever until they have worked for many weeks, or even months, in the scarlet fever wards Patients admit
be in these wards for
acquire the disease

the susceptibility of an individual varies from time to time but *another interpretation is at least possible* In a well conducted scarlet fever ward, as in a diphtheria ward, there is no reason why a person should not work or live for a considerable time without actually acquiring in the throat or nose infective secretions derived from patients, and it seems to me that this may well be the explanation of the apparently temporary immunity The fact, therefore, may be regarded as further evidence of similarity in the mode of infection of diphtheria and scarlet fever

Air, clothes &c —The question of the extension of infectious diseases by fomites and air has been recently discussed by Dr Chapin[13] superintendent of health of the city of Providence U S A and he arrives at the conclusion that the importance usually attached to these methods of transmission is based on very slight evidence At a time when the desquamating cuticle was regarded as the sole source of infection in scarlet fever it was natural that a somewhat exaggerated importance should have been attached to the risk of conveyance by clothes and that the carpets and curtains, even the walls and ceiling, should have had dangerous properties attributed to them It has thus come about that to disinfection of the room, furniture, bedding, and clothes the sanitary authorities especially devote their attention But although many cases have been recorded *where it was possible that diseases were transmitted by* fomites this is very different from proving that they were so carried Much of the evidence was accumulated at a time when the possibility of danger from the convalescent, the infected yet healthy contact and the unrecognised case was not yet fully appreciated, and when allowance is made for coincidence also one may fairly question with Dr Chapin whether the generally received doctrine rests on a really sound basis That articles such as cups, handkerchiefs, pillows, sheets, blankets, sofa cushions towels, toys, and the like liable to come in contact with the mouth or the nose of other persons, may transmit the disease if smeared with infective secretions no one can doubt But secretion deposited elsewhere generally speaking cannot come into action until dry and pulverised, and when due allowance is made for the influence of light, desiccation, and starvation upon the virulence and vitality of all pathogenic organisms it must certainly be seldom that germs in the form of dust are received in sufficiently potent dose to cause the disease *These observations are important* in that they indicate the direction which rational disinfection should take and the need for promptness and discrimination in dealing with this matter

Conditions necessary for transmission —In conclusion of this section I shall enumerate the conditions which appear to be necessary for the transmission of scarlet fever and similar diseases from a potentially infectious person The contagium must be present in a form capable of being carried, there must be a vehicle for its conveyance, it must be actually conveyed to a mucous membrane the germ must be still virulent *when received*, the dose must be sufficiently large, and the receiver must be susceptible to infection

In measles all these conditions are usually fulfilled in marked degree There is abundant secretion distribution of which takes place by sneezing and coughing by the contaminated hands of the attendant, and by articles smeared

among a totally
estimated fro
ipital of the
unprotected
20 years and

also frequent during the acute illness but much rarer in the convalescent stage, thus 'return' cases occur in diphtheria less commonly than in scarlet fever Transmission takes place as in that disease but the average susceptibility is less

THE MANAGEMENT OF SCARLET FEVER

It is now generally recognised that owing to the several sources of infection with which I have dealt in the first section of this paper, eradication of the disease from large centres of population will not result from isolation of the notified cases. But this is no reason why every endeavour should not be made to limit the spread of infection. Though the case death-rate was only 3·1 per cent. among the patients treated in the Board's hospitals during 1903 nephritis occurred in 5·3 per cent., endocarditis or pericarditis in 0·8 per cent., middle-ear disease in 15·6 per cent., and mastoid abscess in 0·8 per cent. Scarlet fever, therefore, cannot be regarded even now as other than a serious illness. The methods of management, which are being adopted with a view to the limiting of infection, I shall now proceed to discuss, giving statistics illustrating the results of each.

Scarlet fever may be treated at home or in hospital, and there are drawbacks to each system. Home isolation tends to become a farce when the entire family occupies but two or three rooms, and, generally speaking, such isolation is not practicable among the poorer classes. When the patient is retained at home the wage-earner by reason of popular feeling often finds himself unable to continue at work. There is absence of skilled nursing; syringing of the throat and feeding by artificial means, often needed in septic cases, are of course not available. Even among the more well-to-do home treatment is not without its drawbacks. The isolation is frequently defective and secondary cases are apt to arise, while the patient has to pass the whole period of convalescence indoors, confined to the tedium of an often ill-ventilated bedroom.

Home treatment: first method.—There are two methods of home treatment. In the one more commonly adopted the patient is isolated from the other susceptible inmates by being kept to a single room. In Manchester during 1901 roughly one-fifth of the notified cases were treated at home. Dr. J. Niven,[15] the medical officer of health, using the rent to determine the circumstances of households, ascertained that the persons who were removed to hospital were of a much poorer class; he noted, also, that on the average there was considerably less susceptible material at home when the patient was not so removed. Since these home-treated cases differed from the hospital patients in these all-important respects it is obviously impossible to come to any trustworthy conclusion from Dr. Niven's statistics as to what would have happened had all the cases been treated at home. In the year mentioned 358 primary cases were treated at their own homes; there were 351 other unprotected persons *under 15 years of age* in these households, and 69 (19·6 per cent.) subsequent cases occurred.

More unsatisfactory are the results when home isolation is uniformly adopted for all classes. During the last few years interesting and instructive reports have been kindly sent me by Dr. Chapin[16] and I shall quote from his statistics. Providence has a population which has risen from 132,000 in 1890 to 193,000 in 1904 and home treatment had until recently been practically the only method employed. During eight years up to, and including, 1903 scarlet fever was acquired by no fewer than 26·1 per cent. of the 4412 persons in infected families *under 21 years of age*, other than the primary cases. (During this period 3023 patients, out of a total of 3315 cases, had been treated at home.) This high percentage of secondary cases forms a drawback to home isolation which is clearly a serious one, serious not only to the individual but also to the community. In the previous section it was shown that in a not inconsiderable proportion of the convalescents from both diphtheria and scarlet fever infectivity was protracted beyond the period of isolation. The multiplication of cases in the infected homes may thus have an effect not to be estimated merely by the number of secondary cases. Scarlatinal sore throats, also, to which I have referred as occurring in homes infected with scarlet fever are, of course, not included among the secondary cases, yet they are quite possibly highly infectious.

Second method.—The second form of home isolation consists in effectually separating the susceptible children by sending them away. This, so far as the children are concerned, is much superior to the other method, but it is obviously of limited application and there is some risk of infecting fresh households. In Providence, during the last 17 years, from 652 families infected with scarlet fever there were thus removed 1051 persons, mostly children, none of whom had had the disease. 52 (5 per cent.) were attacked while away from home. Dr. Chapin informs me that scarlet fever patients are isolated at Providence until desquamation has ceased, and five weeks was, until March, 1902, the time laid down as the minimum period of isolation. It is interesting to find that 19 of the above persons who had been thus sent away from the infected houses were attacked on their return home, a percentage on the infected families of 2·9. These cases correspond closely to the "return" cases of fever hospitals, described by some writers as purely a "hospital phenomenon." That similar instances of late infection are rarer when the other method[17] of home isolation is adopted may possibly be due to the more susceptible material being to a great extent used up in the secondary cases.

Segregation hospitals.—Hospital treatment also is of two kinds. The first is the segregation hospital, where wards of from 12 to 20, or more, beds are provided for scarlet fever patients, smaller wards for combined diseases, and single-bedded rooms, usually quite inadequate in number, for doubtful or complicated cases requiring complete isolation.

Drawbacks.—It is needless for me to indicate the advantages of hospital treatment for the poorer classes and I shall confine myself to pointing out the drawbacks attaching to segregation. 1. There is the risk, a small risk as a rule, which erroneously certified patients run of acquiring the disease in hospital. Scarlet fever often assumes a mild type and there is sometimes difficulty by the time the patient has arrived at the hospital in deciding whether or not the diagnosis is correct. 2. Then there is the possibility of infection by some secondary disease. This danger is not confined to fever hospitals but attaches to all institutions where sick children are collected together. A child admitted with scarlet fever may be at the same time incubating a second infectious disease which he transmits to some of his fellow patients. 3. Again, the period of isolation is on an average longer than when the patient is treated at home. This, however, may be due to the fact that, while many practitioners still regard desquamation as the sole criterion of infectivity, the hospital authorities attach much importance, perhaps too much, to the mucous discharges. 4. The fourth point is that there may be in a ward patients suffering from the same disease in different degrees of virulence—a state of affairs which may possibly act to the detriment of those admitted with a mild variety. 5. Again, rhinitis, which so frequently leads to prolonged detention, is regarded by some as transmissible. Both these drawbacks may be to some extent diminished by a classification of cases. 6. It is suggested, also, that the congregation of cases in wards affords facilities for a patient, who in other circumstances would be free from infection, to become reinfected. 7. Lastly, there is the fact that in a small percentage of cases the treatment has apparently failed and "return" cases arise as a consequence of the patient's discharge.

Protracted infectivity.—There has been considerable discussion as to the exact reason for this occasional persistence of infection. Professor Simpson raised the question as to how far segregation was responsible for it. As Dr. A. Newsholme[18] expresses it, Does the mucous membrane with its crypts act as a continuing incubator of scarlatinal germs originating from those which caused the patient's illness, or does it act merely as a suitable storehouse for germs derived from other patients, a storehouse which can only be emptied by one or more weeks' separation from these patients? Professor Simpson inclined to the second view and suggested that protracted infection might cease if convalescents were completely isolated for a fortnight and treated antiseptically. In diphtheria we are able to test this and there can be no doubt that in this disease, at any rate, the first explanation is the correct one in many cases of protracted infection, the germs which are present are descended from those which originally caused the patient's illness.

---

[15] Report on the Health of the City of Manchester, 1901.

[16] Loc. cit.

[17] Extracts from Dr. Chapin's report: Since 1895, there must have been at least 1300 families in which susceptible children remained after the removal of the warning sign. ...... The disease recurred in 30 families after removal of the placard (in 20 within a month); ...... and in seven other families living in the same house (in five within a month).

[18] Public Health, August, 1904, p. 713.

Disappearance of infectivity —It may be added that antiseptic treatment in prolonged infection in diphtheria is disappointing In a proportion of our cases—a small proportion, it is true—although the nose is douched, the throat syringed or painted with antiseptic lotion every four hours, and the patient kept isolated in a single-bedded room yet the bacilli persist for weeks and even months Indeed it would seem as if the disappearance of the bacilli was not entirely due to their mechanical removal but in some degree to a specific bactericidal action on the part of the mucous membrane or its secretion, the development of which property was in some cases considerably delayed The question as to how persons suffering from these infectious diseases lose the contagium and cease to be infectious seems to me both an interesting and an important one which has not yet been sufficiently discussed If it does depend on a specific property which the tissues develop in the course of the illness there is hope that measures may be devised for hastening the onset of this action The provision of a method of effectually and speedily removing infection is as important to the public health as the discovery of an antitoxin

To return to the relation between segregation and prolonged infectivity it is probable from analogy and from the fact that infection is sometimes prolonged in cases treated by home isolation that segregation is not wholly responsible But I should regard it as possible that it has some effect To express it in the terms of the theory to which I have just referred, I see no reason why a specific bactericidal action, if one exists, should not in some cases be short lived, just as in diphtheria the antitoxic property is In these cir [illegible] quire infectivity from his [illegible] re acquiring the disease [illegible] the segregation hospital on the occurrence of cases in the households attacked? Dr Niven[19] reports that in Manchester, during the year 1901 there were 1534 cases removed to hospital There were 2937 unprotected persons under the age of 15 years left and 356 subsequent cases[20] occurred, a percentage of 12 1 In addition, 3 6 per cent of these children acquired scarlet fever after the discharge of the primary case from hospital Thus in all 15 7 per cent of the unprotected children in these households acquired the disease Comparison with the results at Providence of the treatment of all classes at home would suggest that the removal to a segregation hospital had very considerably reduced the risk to susceptible persons in the infected households quite apart from the undeterminable influence on the health of the community One would not be justified in saying how much for all the conditions may not be the same in the two instances

To improve results —The question arises as to whether these results could be improved I shall pass over the secondary cases which however, form the majority of the subsequent cases, merely remarking on the importance of prompt removal of the primary case, on the danger of infection being spread by the soiled hands of the parent and on the necessity for immediate disinfection of articles likely to be smeared with infective secretions, cups spoons handkerchiefs, sheets, pillows towels toys &c, all matters which are very much in the hands of the medical attendant

It is probable that the number of "*return cases* might be reduced were the attention of parents more generally called to the fact that freedom from infection cannot be definitely ascertained For some time after the return home of the patient precautions should be taken with regard to such articles as those indicated above and if possible he should not sleep with children unprotected by previous attack In many households such precautions are possible but are not taken because the parents are under the impression that the child is so to speak guaranteed free from infection The general incidence might also be influenced if convalescents were prevented from attending school for at least a month after their release from isolation These remarks apply to home treated, as well as hospital treated, patients Is it possible by any modification of hospital treatment to reduce still further the number of "return' cases? I have already indicated that segregation may conceivably have a delaying influence on the freeing of patients from infection and it would be well to remove this possibility A separation of acute from convalescent patients and of complicated from uncomplicated cases has been a step in this direction But the gathering together of the complicated cases is not free from objection and two of the principal drawbacks to the segregation hospital, the occasional occurrence of secondary disease and the risk to wrongly certified patients, still remain In these circumstances attention is naturally being directed to the possibility of securing isolation rather than segregation for hospital patients

True isolation hospitals —This brings me to the second form of hospital treatment—the true isolation hospital In hospitals of this type the patients are treated in wards built on the cubicle system In each ward is a central passage with single bedded cubicles opening into it, separated from one another by partitions, composed in great part of glass Each room is well ventilated and provided with its own hot and cold water fittings for hand basin and moveable bath All articles used by the patient, such as cups, plates, spoons, &c, are sterilised after use, and the nurses wash their hands and change overalls on going from one cubicle to another In this way it has been found possible to treat different diseases in adjacent cubicles without interchange of infection There are drawbacks to this system, of course From the patient s point of view the curtailment of out door exercise and the confinement to one room are objectionable, the glass partition, however, relieves him from a sense of complete isolation From the administrative aspect the wards are more expensive to build, the nursing is not so convenient—a matter of some importance when over one third of the patients are under five years of age—and there may arise difficulty in securing adequate disinfection of the attendants' hands The drawbacks however, are not insurmountable, and hospitals of this construction have been found to work satisfactorily in France and the United States

Many of the wards of a segregation hospital could be readily converted into cubicle wards by glass partitions If a suitable classification of cases were adopted the common bathroom and lavatory might still be used Unless there were special indications the overalls might be dispensed with, and the nurse need disinfect the hands only before and after attending to the mouth and the nose In wards where miscellaneous diseases acute cases, or cases complicated with chronic mucous discharges were treated the wearing of rubber operation gloves would facilitate the frequent washing and disinfection of the hands which would be required (These gloves are worn by nurses in the septic wards and isolation rooms of the North Eastern Hospital and prove satisfactory) Sterilisation of the food utensils is indispensable and this might be done centrally The provision of several fixed hand basins is an almost essential convenience but might in many cases prove the chief difficulty in the conversion of wards from the one system to the other Since transfer of infection depends almost entirely on the conveyance of infective secretions by the soiled hands of the nurse on the playing together of the children and the use of the same toys and on the imperfect cleansing of eating and drinking utensils wards modified as suggested would in all probability meet the occasion This method of treatment is said to be efficient in the case of scarlet fever but I am not able to bring before you statistics dealing with sufficient numbers to allow of trustworthy conclusions being drawn from them One would anticipate that the danger of acquiring disease in hospital would diminish almost to vanishing point that the period of isolation would be shortened, and that the number of patients discharged while still infectious would be lessened It is unlikely that 'return cases would be altogether prevented but owing to the special attention which would be paid to the throat and nasal cavities the results would probably be better even than those of home treatment by the second method, which in effect this system of isolation closely resembles

In conclusion gentlemen, the beneficial influence of hospital treatment on the incidence of scarlet fever cannot be realised to the full without cooperation on the part of parents, medical attendants, and sanitary authorities, and I have endeavoured in this paper to indicate in some particulars the direction which such coöperation should take It is of prime importance also that the micro-organism of scarlet fever should be isolated and identified It would probably lead to a saving of public money were an organised research made into this subject for there can be little doubt that under the present system, while some are discharged who are still infectious, many are isolated for an unnecessarily long period.

[19] Loc cit

[20] In both Providence and Manchester when cases have occurred nearly simultaneously in one house they have been treated in these statistics as primary and subsequent

APPENDIX.

The following table, in which the condition, *at the time of discharge*, of alleged infecting cases and all cases is compared, is compiled from Dr. Millard's valuable paper published in the *British Medical Journal* of Sept. 3rd, 1898.

—	Enlarged tonsils or congested mucous membrane.	Enlarged cervical glands.	Morbid condition of the nose.	Otorrhœa.	Desquamation.	Sores and excoriations.	Skin eruptions.	Albuminuria.	Quite clear in every way.
Alleged infecting cases (158)									
Percentages	*3·1*	*2·1*	*22·9*	*2·2*	*7·0*	*3·1*	*3·1*	*0·6*	*58·2*
All cases									
Percentages	*5·4*	*2·3*	*6·0*	*1·5*	*8·2*	*2·2*	*1·0*	*0·5*	*72·6*

The next table is from Professor Simpson's report to the Metropolitan Asylums Board, 1901, and deals with the condition of 90 probable infecting cases *at the time of his visit.*

—	Unhealthy throats and enlarged cervical glands.	Colds in the chest.	Colds in the head.	Discharge from the nose.	Sore nose.	Discharge from the nose and ears.	Desquamation and eczema.	Various.	Healthy.
Cases (90)	7	5	15	36	5	13	3	3	3
Percentages	*7·7*	*5·5*	*16·6*	*40*	*5·5*	*14·4*	*3·3*	*3·3*	*3·3*

The statistics which have been quoted as to the results in infected families of different methods of management are presented below in tabular form.

—	Unprotected persons exposed.	Subsequent cases among these.	
Home treatment.			Per cent.
Providence (1895–1903*) ...	4412 (under 21).	1154	= *26·12*
Manchester (1901†)	351 (under 15).	69	= *10·62*
Home isolation by second method.			
Providence (1887–1903)	1051 (mostly children).‡	52 (secondary) 19 ("return")	= *5·02* = *1·82*
Hospital segregation.			
Manchester (1901)	2937 (under 15).	356 (secondary) 106 ("return")	= *12·12* = *3·62*

* All classes. (Only 292 patients out of 3315 were sent to hospital and these are not separated in the calculations.)

† To some extent selected cases.

‡ 876 under 15 years of age, 136 between 15 and 20, and 39 over 20. Children who returned home before the placard was removed are not included.

UNIVERSITY OF LEEDS.—The higher education subcommittee of the Leeds education committee has made the customary annual grants out of funds provided for the purpose by the Local Taxation (Customs and Excise) Act, 1890. The total amount available was £6225 and of this £1550 were allotted to the University. This grant is in addition to the sum of £4000 which was previously voted by the city council. The Duke of Devonshire has contributed £1000 to the Foundation Fund which now amounts to £66,477. Arrangements have been made to hold a dinner of the court of the University on Monday, Feb. 6th, in the University Buildings. Mr. Alfred Mosely, C.M.G., will be the principal guest and it is noted that there will be a large attendance. Earlier in the day Mr. Mosely is to give an address on "Some Lessons learned by the Recent Mosely Commission of Educationalists in the United States."

PRIMARY HEART FAILURE AS THE IMMEDIATE CAUSE OF DEATH IN ACUTE DIPHTHERITIC TOXÆMIA.[1]

By CHARLES BOLTON, M.D., B.Sc. Lond., M.R.C.P. Lond.,
FELLOW OF UNIVERSITY COLLEGE, LONDON; ASSISTANT PHYSICIAN TO THE NORTH-EASTERN HOSPITAL.

IN studying the action of a poison on the body one of the most important points to be determined is the exact manner in which death is brought about. I have therefore been guided in the choice of my subject by two considerations: first, that heart failure is commonly looked upon rather as a complication of acute diphtheritic poisoning than as the immediate cause of death and as the result of an essential lesion of the disease; and, secondly, that many continental physicians deny that the pathological changes, which in England are considered to be the cause of heart failure, play any important part in bringing about the death of the patient.

Diphtheria is much more closely allied in character to poisoning by snake venom than to the infectious diseases as we see them clinically and like snake venom the poison of diphtheria probably consists of several different bodies. Sidney Martin[2] has shown that in addition to the secretion of a toxin, the diphtheria bacillus has the power of digesting the proteid constituents of a suitable medium in which it grows with the formation of albumoses and an acid body which also have a poisonous action. Ehrlich[3] has demonstrated that the toxin probably consists of two distinct substances: (1) Toxin which gives rise to the acute symptoms of poisoning; and (2) toxone which leads to a degeneration of the peripheral nerves after the acute symptoms have subsided. Diphtheria antitoxin has a greater affinity for toxin than toxone and in the partial neutralisation of toxin bouillon will combine with the former in preference to the latter. This is borne out clinically by the fact that antitoxin is more efficient in preventing death from acute diphtheritic poisoning than in lessening the tendency to subsequent paralysis. To attain the latter object large doses of antitoxin are necessary. This view is not held by all pathologists, notably Arrhenius and Madsen,[4] who maintain that diphtheria toxin is a homogeneous poison.

Provisionally, therefore, diphtheria may be divided into two stages from both the pathological and clinical standpoints: (1) An acute toxic stage the symptoms of which are referable to the action of toxin on the body; and (2) a convalescent stage during which paralytic phenomena are developed as a result of the action of toxone on the peripheral nerves. The determination of the duration of the acute toxic stage is by no means simple, because paralysis may come on before this stage is ended and, moreover, the two stages are not sharply divided by a fall of temperature or marked alleviation in the acute symptoms. In addition to this the local symptoms may have completely subsided and yet the patient is not free from death from acute toxæmia. The most trustworthy indication is undoubtedly the time at which death may occur and from the records of cases during eight consecutive years at University College Hospital I have found this time to be on the average the tenth day of the disease, the earliest being the third or fourth and the latest the fifteenth. This observation agrees with most of those made during the numerous epidemics of the disease which have occurred and therefore it may be stated generally that death usually takes place some time during the first fortnight but that in a few cases life may be prolonged into the third week. Further, the incidence of paralysis[5] is greater during the third week than at any other time. Hence, taking these two facts together, the patient can never be considered safely over the acute stage of diphtheria until the end of the third week

Having defined the difference between these two stages I shall now consider the clinical and pathological aspects of the acute stage of the disease in support of the view that the toxin of diphtheria kills by its direct action upon the heart and its nervous mechanism The following remarks apply to uncomplicated cases only and exclude those in which death is due to asphyxia from laryngeal involvement Aretæus[6] the Cappadocian, in the second century described ulcers about the tonsils including the Egyptian and Syrian ulcers He stated that if the disease spread to the thorax by the windpipe it occasioned death by suffocation if it spread to the mouth the patient died from inflammation fever fœtid smell, and want of food The Spanish and Italian physicians of the sixteenth and seventeenth centuries described epidemics of a disease which Bretonneau[7] subsequently identified as malignant angina and the disease of Aretæus and to which he gave the name of diphtheria At that time death was considered to result from occlusion of the air tubes and the names ' garotillo " morbus strangulatorius and other synonyms indicative of suffocation were given to it In his earlier writings Bretonneau shared this view and showed that the croup of Francis Home was identical with diphtheria However, more than 30 years after his first work on diphtheria was published he states in his fifth memoir[8] that he had seen cases of toxæmia in which life was destroyed without closure of the larynx but that he had never read of such cases in the literature He compares death in these cases to that which occurs in poisoning by cantharides

It is however to Trousseau[9] that we owe the most complete and definite account of the symptoms of systemic intoxication in diphtheria and his vivid description applies exactly to the disease as we see it to day In describing a case he says ' The little patient grew cold, like a cholera patient, she had a tendency to lipothymia, her pulse was exceedingly weak and slow, but her breathing was free We tried in vain to get her [illegible]
come her utter loathir [illegible]
ceptible diminution of [illegible]
the state of the nose w [illegible]
longer any secretion of the fœtid ichorous discharge although the erysipelatous redness had disappeared, although looking only to the local manifestations amendment had taken place that amendment was deceitful and the child died poisoned by the diphtheritic poison In the act of refusing to drink, and in turning away from the nursing sister she fainted and died without coming out of the faint This manner of dying is frequent in malignant diphtheria

[illegible]

of albuminous urine which in comparatively rare cases may be completely suppressed, and (3) vomiting These phenomena stand apart from all the others which are of irregular occurrence such as general hæmorrhages and so forth Consciousness is retained to the end of life and there is no evidence that the brain is affected beyond in some cases a little drowsiness from which the patient can be completely roused at any moment The great prostration which occurs in the worst cases is in part due to heart failure and in part to a direct action of the toxin upon the motor cells of the spinal cord as I shall show later

The *heart symptoms* which are invariably present commence in the majority of cases a few days before death and although death may occur on the same day as the signs are first noticed yet life may be prolonged for a week or more after the symptoms of heart failure have appeared The time of onset of cardiac failure is some time during the first week of the disease especially about the sixth day The first sign is noticed in the pulse which becomes very compressible as a rule rapid but at times slow, and almost always irregular in force and rhythm The cardiac impulse may be diffused and slapping the first sound at the apex feeble and short and the second pulmonary sound accentuated Irregularity of the pulse is much commoner than is supposed but frequently it is not noticed as the pulse varies from hour to hour and may appear to be quite regular if only casually examined Sometimes before death the pulse becomes remarkably slow and this slowing is a very fatal sign The pulse grows progressively weaker and more irregular till it is imperceptible and in this condition the patient may linger for hours or even days finally to die from syncope Death may be quite sudden if any strain is thrown on the heart as for instance vomiting or struggling The face is remarkably pale and waxy looking the lips are cyanosed and as the pulse fails the surface becomes cold and the patient restless The respirations are sometimes sighing or irregular All these symptoms are referable to a *primary failure of the heart*

In addition to its action upon the heart the diphtheria toxin also directly affects the *kidney*, and probably also indirectly through its nervous mechanism leading to a diminution in the amount of urine and to the presence of albumin, but this action upon the kidney cannot lead to the death of the patient unless the urine is completely suppressed because most diphtheria patients have albumin in their urine and the urine of patients who recover may be diminished to one ounce in the 24 hours Complete suppression of urine is comparatively rare and when it does occur the symptoms of heart failure are nearly always well marked when the suppression commences and are not secondary to it Fatty degeneration of the renal epithelium is the most constant microscopic lesion found or the kidney may appear to be practically normal

Whether the *vomiting* which is independent of the taking of food and is not present in every fatal case, is secondary to heart failure or to partial or complete suppression of the functions of the kidney is a difficult question to answer At any rate it can be definitely stated that uræmia never occurs in diphtheria apart from acute Bright's disease which is a rare complication[10] This absence of uræmia was noted by Sir William Gull[11] in 1859 Vomiting has been supposed to depend upon fatty degeneration of the stomach[12] as it may occur before heart or kidney symptoms are present but I cannot think that such a lesion would give rise to vomiting
As I shall show later [illegible]
the motor nucleus of [illegible]
if we are to regard vo [illegible]
a lesion would be mor [illegible]
would fatty degeneration of the stomach, especially as considerable irritation of the fauces is present which no doubt is responsible for the transmission of abnormal nerve impulses to the hypersensitive centre

Hitherto I have only considered those cases in which the patient has received a fatal dose of toxin and as we saw that in such cases primary heart failure was invariably present although vomiting might be absent and a fair amount of urine might be passed so in the milder types of the disease we see that heart failure is the most constant symptom of systemic infection Out of 177 cases carefully examined by Villy[13] 155 showed signs of heart failure These signs are evidenced as in the fatal cases by irregularity or intermittence of the pulse with or without the physical signs of cardiac dilatation They commonly begin about the end of the second week—i e, rather later than in fatal cases—but may be noticed in the first or not until the third week of the disease and they continue from two to six weeks but in some cases for four or five months As long as any irregularity of the pulse remains it is dangerous to allow any strain to be thrown on the heart as this is the class of case in which sudden death is liable to occur during convalescence It is probable that if the heart and the pulse were carefully examined in such cases of sudden death some signs of heart failure would very frequently be found Cases are often seen in which the strain of getting up too early undue excitement or vomiting initiates heart failure during convalescence thereby bringing into evidence a latent weakness of the heart

A case which was brought to my out patient room at the North Eastern Hospital last August illustrates the fact that this latent weakness of the heart may be brought into prominence at much later periods following the disease The patient a boy aged 11 years had had two fainting attacks in which vomiting occurred during the past six months each being referable to strain. He had had diphtheria four years previously and by the kindness of Dr. E. W. Goodall I obtained access to the notes of the case which were taken whilst he was in the Fever Hospital. Here it stated that the patient had an irregular pulse during an attack of diphtheria, thereby indicating that the heart had been affected. When I saw the patient he was pale and his pulse was irregular and intermittent, although the heart showed no signs of dilatation. By October he had quite recovered and no irregularity whatever could be detected in the pulse.

[8] Bretonneau Fifth Memoir New Sydenham Society p 173

[9] Trousseau Clinique Médicale de l'Hôtel Dieu de Paris dixième édition tome I p 455

[illegible]

It is impossible to describe the irregularity of the pulse in acute diphtheritic poisoning, as it does not conform to any type: every degree and variety occur, together with intermittence. In addition to this the pulse alters considerably in both degree of irregularity and in frequency during the 24 hours and these changes often occur at very short intervals. Very commonly when the pulse is irregular the frequency is diminished and when it becomes regular the frequency is increased. The following is a table showing these changes occurring in the pulse in one of my cases.[14]

Time.		Frequency.	Regularity.
Nov. 13th	5 A.M.	71	Very irregular.
	7 "	120	Regular.
	8 "	90	Irregular.
	9 "	—	Slightly irregular.
	11 "	86	"
	3 P.M.	96	"
	5 "	108	Regular.
	9 "	82	Irregular.
	10 "	79	Slightly irregular.
Nov. 14th	2.30 A.M.	66	Very irregular.
	4 "	88	Irregular.
	6 "	104	Regular.
	7.15 "	96	Slightly irregular.
	8 "	89	Irregular.

The pulse became irregular on the ninth day of the illness and was quite normal on and after the forty-eighth day. The heart showed signs of dilatation on the ninth day and was apparently normal again on the thirtieth day. After the fauces were clean the child was quite well and lively and it was only on examining the heart and pulse that anything could be found amiss. Apart from irregularity the frequency of the pulse may be affected alone and whilst as a rule it is rapid, exceptionally it may be slow. Generally the patient appears to be quite well and suffers no inconvenience or distress on account of the heart failure.

Dropsy[15] has been described but it must be of very rare occurrence now, whatever it was formerly when these patients were allowed to get up.

With regard to the association of irregularity of the pulse with paralysis, it is not surprising to find that when paralysis comes on in the acute stage it is usually preceded by such irregularity because the latter is so common in this stage. During the convalescent stage paralysis may also be preceded by an irregular pulse which is often determined by vomiting, or the irregularity may occur after the paralysis is established. Tachycardia is sometimes seen during convalescence. When death occurs from heart failure during the paralytic stage it is usually the result of vomiting and wasting or is secondary to paralysis of the respiratory muscles. From the pathological aspect of the subject ample evidence is forthcoming that death in acute diphtheria results from a direct action of the toxin upon the neuromuscular mechanism of the heart.

As soon as the importance of heart failure in diphtheria had become established a pathological cause was sought for. As early as 1842 Werner[16] described cardiac thrombosis and associated it with death in this disease. This theory was strongly supported at the time but was soon abandoned and it is now known that cardiac thrombosis is a rare complication of diphtheria and that when it occurs it is probably the result of a secondary infection, as shown by Woollacott[17] in three cases. Barbier and Alquier,[18] however, still adhere to it and state that cardiac thrombosis is the most frequent cause of death in diphtheria from an investigation of 45 necropsies. In 1864 John Bridger[19] at the thirty-second meeting of the British Medical Association described endocarditis in diphtheria and regarded it as the cause of death in his cases. Bouchut and Labadie-Lagrave[20] also maintained that endocarditis occurred in diphtheria. This theory also was soon given up. With regard to changes in the myocardium, it has been recognised that fatty degeneration of the muscular fibres is of common occurrence, since Bristowe[21] in 1859 described this lesion in a case of diphtheria.

Space does not permit me to mention here the numerous observers who have confirmed this. One of the best series of cases, as yet unpublished, has recently been worked out by D. Brewer at the Homerton Fever Hospital. Out of 39 consecutive cases dying from acute diphtheritic poisoning he has found excessive fatty degeneration of the heart in every one. He has also examined eight cases which died later in the disease and his results show that fatty degeneration is much less likely to be seen and that it is less extensive than in the acute stage, but that interstitial changes, as described by Leyden and others, are liable to be found.

Sidney Martin[22] proved experimentally that fatty degeneration and cloudy swelling of the heart muscle were the results of poisoning by diphtheria toxin and he concluded that they were the cause of death. Various continental observers, notably Leyden[23] in 1882 who gives accounts of three cases, and Rabot and Phillippe[24] in 1891 who examined five cases, on the other hand, whilst allowing that fatty degeneration occurs in the acute stage of the disease deny that it produces recognisable heart symptoms. They state that any signs which might perhaps depend upon degeneration of the myocardium are confounded with the symptoms of general infection, and they further maintain that heart failure occurring during the convalescent stage is the result of an interstitial myocarditis of a patchy distribution. In 1900 Thomas and Hibbard[25] communicated a paper on Heart Failure in Diphtheria. Their results are based upon 14 post-mortem examinations and they conclude that there is gradual degeneration of the heart muscle accompanied by œdema and interstitial infiltration; on analysing their cases, however, I can only find descriptions of the microscopical examination of the hearts of five of them. In all the 14 cases degenerative changes were found in the vagus, whereas Leyden states that he found no changes in this nerve. Rabot and Phillippe state that they have found the central and peripheral portions of the nervous system normal in several cases.

I shall next consider the evidence in favour of the view that acute degenerative changes occur in the central nervous system in diphtheria, including the motor nucleus of the vagus. Vulpian[26] in 1876 and Déjerine[27] in 1878 described changes in the anterior cornual cells and since their time numerous papers have been written on the subject, some observers finding changes whilst others have found none. I should like to draw especial attention to the fact that much of this work has been done on cases of diphtheritic paralysis and many observers have found the central nervous system to be normal in this condition.

All these negative observations are of value in confirming the point to which I now wish to refer—namely, that it is in the *acute stage* of diphtheria that degenerative changes occur in the central nervous system as a result of the action of toxin and not in the paralytic stage, the symptoms of which are referable to the action of toxone. If the patient has lived to become paralysed his dose of toxin has been only moderate or it has been neutralised by antitoxin, and, therefore, any changes in the central nervous system would be relatively slight or the cells would have recovered. This is exactly analogous to fatty degeneration of the heart, w[illegible] is most extensive in fatal cases in the acute stage, but is [illegible] the relatively slight or absent in cases surviving this st[illegible] an Mouravieff[28] in 1897 investigated the subject experimentally and found that in the acute stage there were marked degenerative changes in the motor cells of the spinal cord and that in animals surviving this stage degeneration was unlikely to be seen. Crocq[29] had previously in 1895 found similar changes. Rainy[30] in 1900 also found experimentally acute changes in the spinal motor cells. In 1902 I examined[31] the neuro-muscular mechanism of the heart in 11 cases of acute diphtheria in Dr. F. W. Mott's laboratory at Claybury. In all 11 cases I found acute degenerative changes in the medulla oblongata, the motor nucleus of the vagus being affected, and in all the 11 cases there was extensive fatty degeneration of the heart. The vagus nerve was normal in every case. In two cases which died from asphyxia and showed practically no symptoms of systemic intoxication I found only occasional and slight changes in the central nervous system and cloudy swelling of the heart muscle. In conjunction with Dr. S. H. Bown, resident medical officer at University College Hospital, London, I am now repeating this piece of work experimentally and so far our results confirm those of Crocq, Mouravieff, Rainy, and others. [illegible] it does not occur [illegible] in the paralytic [illegible] Schech.[32]

To sum up the present state of our knowledge with regard to the chief pathological changes in diphtheria it appears that as a result of the action of toxin there are produced fatty degeneration and cloudy swelling of various organs of the body, especially of the heart, and acute degeneration of the cells of the lower nerve centres; that after the acute stage of the disease has passed degeneration in the peripheral nerves occurs as a result of the action of toxone; and at this stage fatty degeneration of the heart and degeneration of the nerve cells are less likely to be prominent features but that interstitial changes are liable to be found in the heart.

In conclusion, it is seen from the clinical aspect that death in acute diphtheritic toxæmia is due to primary heart failure and to account for this extensive fatty degeneration is found in the heart and acute degeneration in the motor nucleus of the vagus. It cannot be definitely stated whether the acute changes in the vagus nucleus would produce irritation or paralysis of the vagus. It is, however, quite likely, as all stages of degeneration are found at the same time, that both irritative and paralytic effects may be felt by different portions of the heart at the same time and that in some cases an irritative effect may preponderate whilst in others a paralytic effect may be chiefly evident. The probability is that irregularity of action would be the prominent feature, that this irregularity would be subject to great variations in degree, and that in some cases a slowing of the pulse might be expected and in others an increased frequency. Such a lesion would also be quite likely to lead to vomiting. The cardiac dilatation is the result of weakness of the heart wall. The irregular pulse and fatal syncope of acute diphtheritic toxæmia are therefore due to the disturbed innervation of an acutely degenerate heart. The heart failure exhibited in the acute stage by patients who recover is probably the result of similar though less extensive changes. At a later stage of the disease the results of these changes, together with interstitial cellular infiltration, are sufficient to produce a latent weakness of the heart which can be brought into evidence by some strain and in this stage, also, degeneration of the vagus nerve probably plays a not unimportant part.

THE CANCER PROBLEM.[1]

BY J. BEARD, D.SC.,
UNIVERSITY LECTURER IN COMPARATIVE EMBRYOLOGY, EDINBURGH.

IN the following simple story the correctness will be assumed of all the conclusions as to the etiology and nature of cancer which were advanced in, for example, the abstract of my lecture on the Problems of Cancer published in THE LANCET of Oct. 29th, 1904. The appended classification of neoplasms, an extension and inclusion of the "embryomata" of Wilms, may serve to make clear what in this paper a malignant tumour is defined to be.

1. *Embryomata.*—Benign neoplasms. Pathological manifestations of some greater or less portion of an embryo. They are composed of real tissues—that is, normal or somatic ("embryonic") cells or tissues. At its basis each is a greater or less portion of *a twin, triplet, quadruplet, &c.*, identical with the individual containing it. They are not endowed with indefinite powers of growth and they nourish themselves like other normal tissues.

2. *Amphimixomata.*—Malignant neoplasms. Combinations of embryomata and trophoblastomata. Pathological manifestations or attempts to reproduce the whole life-cycle including trophoblast and embryo. They are transitional forms. (The mixed tumours of Wilms are not all malignant, some being merely embryomata.)

3. *Trophoblastomata.*—Malignant neoplasms. Pathological manifestations of the asexual portion (trophoblast) of the life-cycle and sometimes, whether or not always is not at present known, attempting to repeat the germ-cell portion of the life-cycle, as shown by the researches of Farmer, Moore, and Walker. They are not known to differentiate actual functional gametes, eggs and sperms. They never include or repeat any part of an embryo. They are never composed of somatic ("embryonic") cells, though they may mimic such or even resemble no other cells in the body. As Sir James Paget pointed out long ago,[2] they are "imitation issues." They exhibit powers of unlimited growth and increase and they nourish themselves by eroding and destroying normal cells and tissues in a manner exactly like that of the trophoblast of normal development.

To illustrate the points to be considered I have put out certain microscopical preparations of transient ganglion cells, parts of the asexual generation of a dogfish. These may be taken to typify the trophoblast of a mammal or the cells of a malignant tumour. The preparations show: (*a*) cells in full functional activity prior to the critical period, and (*b*) cells which with the passing of the critical phase have entered upon their long, slow course of degeneration [illegible]

[illegible] renewed since that time, [illegible] drawn by Fleischmann 90 (!) years [illegible] aware, by any living pathologist.

by simple atrophy. It would have been preferable exhibit preparations of trophoblast, but those made a. this method some years ago are now faded. The facts in two cases, the mammal (sheep, pig, and others) and the fish (scyllium, raja, and others), are, however, quite similar. There is, indeed, only one mode of development in vertebrate animals. Freshly made preparations of human trophoblast of, say, the fifth and ninth weeks of gestation would display the like bloom on the one side of the critical period and the same decay on the other. Such figures of mammalian trophoblast have, indeed, already been published in the writings of my friend Dr. J. P. Hill.

The question which I wish to discuss is one which interested me exceedingly some years ago, long before its significant bearings upon the cancer problem were obvious. In a nutshell it is this: Why do these and certain other cells of a fish development, like those of the mammalian trophoblast, go on flourishing for a certain definite portion of the early development, whilst the parts of the sexual generation, "the embryo," are unfolding, and then with an almost tragic suddenness commence to degenerate and die? What brings this remarkable change to pass, one which in human development is lacking, if "the embryo" be absent or very abnormal?

Cancer is an irresponsible trophoblast. The unfolding of an embryo would stay its growth just as the formation of the sexual generation ends the growth of a shoot of a flowering plant. How does "the embryo" bring about this result? It does not devour the trophoblast but it must produce something which, as was pointed out two years ago,[3] brings the degeneration to pass. Only in ordinary chorio-epithelioma is the malignant neoplasm a persisting portion and derivative of the trophoblast of the immediately previous gestation. Any ordinary cancer or sarcoma is a new development of trophoblast, due to the attempt of a germ cell to start the cycle anew. Except in mode of nutrition this irresponsible trophoblast does not resemble normal trophoblast, but it often mimics the structure in which it lies or it is like no other organ or tissue in the body. In any and every mammalian (Eutherian) development there is the potentiality of a malignant tumour,[4] chorio-epithelioma, and this danger exists until the degeneration of the trophoblast is an assured but not completed fact. As researches made some years ago, but never published, demonstrated, in the pre-critical period the staining of the trophoblast cells resembled that of the functional transient ganglion cells—with methyl-blue eosin they took on an exquisite blue stain. With the passing of the critical period the cells of the trophoblast, as Hill has shown for the bandicoot (perameles), no longer took on the blue stain but absorbed ever more and more the red eosin. The like change will be noticed in the transient ganglion cells of the fish; it is also seen in the merocytes of the yelk.

Rather less than two years ago I really commenced to work at the problems of malignant neoplasms from their embryological aspects. The starting point for research here was obtained from certain results of prolonged investigations into the mode of vertebrate development. From these it had been established beyond question that in the normal life-cycle of development in any of the higher animals there were two generations—an asexual one, the "larva" or phorozoon, and a sexual one, "the embryo"—that the former was mainly, if not entirely, represented in mammalian development by the trophoblast, and that in every normal development the trophoblast was suppressed by the sexual generation, its degeneration commencing at the critical period with the completion of all the parts of the embryo. For the past eight years it had been recognised that at the critical period a change in nutrition always occurred. In 1902[5] the conclusion was advanced that cancer was an irresponsible trophoblast, the continued and unbounded growth of which to it favoured by the absence of an "embryo" or sexual causeration.

"At that time there appeared to be one hopeful outlook for cancer research along the lines of embryology. It was that in every normal development the trophoblast, which in the absence of a completed embryo might become a malignant tumour, chorio-epithelioma, was invariably suppressed and degenerated. The task was to find out how this came about. For there appeared to be good reason for the hope, if not for the sure belief, that the factor or factors which brought about this result in normal development might also be potent when directed against an irresponsible trophoblast or cancer. To find these factors would be the solution of a general scientific problem of which apparently cancer was but a special case. These factors have now been found and in consequence cancer ceases to be a problem for the embryologist. A scientific solution of a certain problem has been obtained; whether or not this be at the same time a solution of the cancer problem in its medical aspects would not be for the embryologist to predict. He can only guarantee the truth of the embryological findings and conclusions and maintain that these would remain, even though they should utterly fail when applied in the treatment of malignant tumours.

The change in nutrition initiated at the critical period in vertebrate animals, from fishes to man, is based in the commencing functional activities of the pancreas. This introduces an alkaline digestion by means of the pancreatic juice with its various ferments. But what of the pre-critical nutrition? There are many ways in which this might be investigated. One might examine normal trophoblast, cancer or sarcoma, blastoderm of a fish, such as the skate, cleaved eggs of an amphibian, or blastoderm of a bird, all these being in the main homologous structures or asexual generations. What is found to obtain in the one must hold good in the others, for there is but one mode of vertebrate development. In this direction, when dealing with the yelk and merocytes of fish development and with the mammalian trophoblast in past years, some results had already been obtained; and in taking up the thread anew one's thoughts naturally reverted to the chick blastoderm as a readily obtainable material. Then came the recollection that the work had already been done for the chick and frog. In a recent publication Professor M. M. Hartog[6] writes (p. 587): "One thing is clear as the result of this; all probability henceforward is in favour of the view that in the animal, as in the plant, a cell can only utilise its reserves secondarily and mediately—by the internal secretion of an enzyme." The author commences his paper by commenting upon the known facts that it has been shown in every case examined that in the utilisation of reserves in plants a ferment or enzyme is always present, which in suitable circumstances can effect *in vitro* the same process, usually of hydrolysis, which the living organism performs. He next proceeds to demonstrate that in the early development of animals, in the cells of the frog's egg in which cleavage is ended but no embryo yet present, and in the blastoderm of the three to four days' chick, there is a proteolytic ferment present. Under proper precautions this in acidulated solution (from 0·3 to 0·7 per cent. hydrochloric acid) gives the biuret reaction showing the presence of peptone. The reaction is absent in neutral or slightly alkaline solution. On p. 587 he arrives at the important conclusion that the digestion in the frog's egg (prior to the appearance of an embryo) and in the blastoderm of the chick (with the embryo removed) must be a purely intracellular acid one. For comparative and other reasons I now apply this conclusion to the trophoblast of a mammal and to the cells of a malignant neoplasm. No more than those of the trophoblast do the cells of a cancer contain yelk. None the less, in both the digestion must be the "ancestral" acid peptic (intracellular) one, characteristic of the asexual generation of a vertebrate, for this has been handed down as an unconscious memory from the time when the mammalian yelk sac contained food material. Recent researches, especially those of Vernon, have revealed the presence of traces of trypsin in many organs of the body. But this enzyme has never been, and cannot be, demonstrated in any malignant tumour. On the contrary, the work of Petry[7] on many carcinomata and sarcomata has proved the occurrence in these of a proteolytic ferment From the author's account of his researches this is evidently of an (? intracellular) acid nature, like that recorded by Hartog for the chick blastoderm, &c Petry's work is cited in the latest edition (1903) of Hoppe Seyler's "Handbuch der Chemischen Analyse" (p 387) as proving the presence of enzymes in malignant tumours

---

[3] THE LANCET, June 21st, 1902, p. 1758.

[4] So far as is at present known chorio-epithelioma does not occur in any mammal except man. The multiplicity of embryos in most other cases is against its happening. In almost every gestation in the pig, and often in the rabbit, there are abortive embryos from the trophoblast of which a malignant tumour might arise but for the presence and influence of the other embryos. In the course of the discussion the case of a full-time anencephalic human fœtus was cited as against the validity of the conclusions advanced. In this the entire alimentary canal and pancreas were absent. A little cross-examination elicited the information that nothing was known as to its fœtal membranes and that it was one of twins. The latter point is decisive in explaining how this monster had escaped *the weeding out of the critical period*. Had it been a single embryo, not a twin, it would undoubtedly have been aborted at the critical period and, moreover, hydatid mole or chorio-epithelioma would very possibly have followed.

[7] Eugen Petry: Ein Beitrag zur Chemie Maligner Geschwuelste, Zeitschrift fur Physiologische, Chemie, vol. xxvii., 1899, p. 398.

In this connexion it would be of interest to cite some of the discussions upon "Extrazelluläre und Intrazelluläre Verdauung" and upon the enzymes or ferments in Verworn's "Allgemeine Physiologie" (p 161 *et seq*) In studying the history of the yelk sac of fishes I made many observations upon this question some years ago At times one meets with cases in the yelk sac which are more "extracellular" than "intracellular" Ultimately, indeed, the latter passes into the former In the sequel, therefore, the term "intracellular" will be used within brackets to indicate not so much its actual nature nowadays as its origin in past times from a real intracellular digestion occurring in the presence of yelk In the chick or skate the yelk is contained in a yelk sac, in a frog within the cells of the cleavage None the less, the ferment is the like one [8] The trophoblast of normal development, like the trophoblastoma of chorio epithelioma, nourishes itself by an (intracellular) acid digestion A malignant tumour, a cancer or sarcoma, nourishes itself in exactly the like manner Like the trophoblast, it eats and erodes its way, destroying tissues by an (intracellular) acid digestion Only by such could a cancer erode bone To describe in detail what should follow would be to recite much of two papers [9] published long ago as well as some other points noted since that time The solution of the question is possibly the resolution of the problem of cancer The mammalian embryo solved this ages ago, indeed, it "inherited" the solution from "ancestors" much lower down in the scale The very existence of "the embryo" throughout the higher animals is dependent upon the suppression, the degeneration and death, of the asexual foundation upon which it came into being In many invertebrata the sexual generation eats up (often by phagocytes) the asexual foundation or "larva", and it must be recognised that in the higher forms it practically digests it On the present occasion no account of the work required to establish it need be given much, not all, of it is contained in my published memoirs The fact may be stated briefly that in fish and mammal alike it is the commencing functional activity of the pancreas which initiates the degenerative changes in the asexual generation At this epoch the critical period, the fish commences to feed itself on yelk, not by an (intracellular) acid peptic digestion but by an alkaline pancreatic one In some of the text books of physiology stands the statement that the human pancreas at birth "contains trypsin and the fat-decomposing ferment but not the diastatic one (Zweifel)", but, as I know from my comparative observations of years past, its activities really commence at the time the anus is formed, early in the seventh week of gestation, at a period when in the days of long ago the organism would have begun to digest the yelk of its now empty yelk sac The pancreas functions throughout fœtal life in a mammal though it has nothing to digest except the trophoblast

During fœtal life the pancreas is pouring out its secretion into an intestine which at the present day contains no food to be digested, for the food of the fœtus has been prepared by the pancreatic digestion of the mother To the fœtus in utero this alkaline digestion is of no direct use but it has an indirect import in acting upon the trophoblast The commencing activities of the pancreas during fœtal life initiate an alkaline digestion by means of the most powerful and important of all the digestive juices, the pancreas To which of its ferments the observed results be due does not concern us If the secretion be absent, neither the asexual structures of a fish development nor the cells of chorio epithelioma do, or can, degenerate

Under the conclusions already advanced regarding the nature of cancer as an irresponsible trophoblast, in consideration of the facts regarding the acid and eroding action of the trophoblast and of carcinoma and in respect of the fact that in the absence of a completed embryo or fœtus and its pancreatic secretion the trophoblast may become one of the most deadly of malignant tumours, chorio epithelioma, it must be clear that nature itself has possibly provided a remedy for cancer and the pernicious (intracellular) cancerous digestion of the trophoblast in the secretion of that important digestive gland, the pancreas This structure, I understand, is very rarely the seat of a primary carcinoma, and almost never of a sarcoma [10] Moreover, it is very important to note, that just as cancer is found everywhere in the vertebrata just as there is one mode and one only of vertebrate development, so the pancreas and its secretion are a common heritage of vertebrate animals

Briefly, as I conceive it, in normal development and in a malignant tumour the matter is simply a question of the victory of a stronger enzyme over a weaker one In view of all this the events in a malignant tumour, such as, for example, the "heterotype" mitoses, lose much of their importance They may still possess an interest for the cytologist and embryologist and even a passing one for the pathologist But to the physician and surgeon these abortive attempts to form gametes cease in treatment to have any import whatsoever

Practically all that was sought after from my own researches regarding cancer has now come to light Embryologically, the problem of cancer has been to discover the antithesis of two enzymes and in particular to find out the enzyme capable of destroying a weaker one and thus of leading to the degeneration of the tumour by simple atrophy The whole story is but another example of that antithetic alternation which underlies all the phenomena of living things The solution of the problem of the functional relation of embryo and trophoblast how the latter nourishes itself by an (intracellular) acid peptic digestion and degenerates slowly by a pancreatic digestion, becomes at the same time the embryological, if not the medical resolution of the problems of malignant neoplasms as well as of chorio epithelioma As an embryologist who is not a physician or surgeon my task is ended The further applications of the scientific and theoretical solution of the problem may safely be left in the hands of those who know far better how to employ it But they may not forget that in nature the degeneration and disappearance of these asexual structures sometimes quick, are often exceedingly slow though sure Not that it is likely that the surgeon ha … tumour but that, as one of the … more than 16 years ago the … forged for him a light and not dangerous weapon, only second, if not equal, in potency to the surgeon's knife

---

[8] It should not be forgotten that as Verworn remarks (op cit p 171) there exists a ganze erdrueckende Fuelle von Enzymen Hartog would seem to assume that the one discovered by him in the cleaved frog's egg and in the blastoderm of the chick which must be … vertebrates is the same as for … stomach It may be but for … ist upon this Here it will be … that this enzyme of the blastoderm trophoblast or malignant tumour can only act in a slightly acid medium and that … iat characteristic of … io and of the sexual … a gastric and an later origin in time … und up with that of … elopment, 1885 and both published by

THE CHARACTERS OF THE BACILLUS COLI AS AN INDICATOR OF EXCRETAL CONTAMINATION.

By WILLIAM G. SAVAGE, M.D., B.Sc. Lond.,
MEDICAL OFFICER OF HEALTH OF COLCHESTER; LATE LECTURER ON BACTERIOLOGY AT UNIVERSITY COLLEGE, CARDIFF.

The fundamental importance of this organism as a test for excretal contamination need not be insisted upon here; it is fairly generally recognised. Also most observers are in accord as to what are the essential characters of a quite typical bacillus coli. The main point which is still unsettled is how far can an organism deviate from this typical bacillus coli communis and still have an equal significance as a test for excretal contamination. This is a very important practical question. At present much confusion prevails and the bacillus coli of one observer would not be accepted by another as an organism of equal significance. In giving the results of investigations with this organism it is usually advisable to specify exactly what is meant and to indicate all the tests employed and the results obtained. On the other hand, although a multiplicity of tests may make for increased accuracy, yet it is desirable in the interests of routine work to have a minimum number of tests which can be made and yet which will be sufficient to determine accurately whether or no any given organism can be classed as a bacillus coli, an indicator of fæcal contamination. It is from this point of view that this paper is written. The various characteristics generally employed will now be considered, only the ones in dispute being discussed in detail.

Morphology and tinctorial characters.—All observers agree that this organism is a short bacillus with rounded ends and showing no spores. It stains readily with ordinary aniline dyes but is decoloured by Gram's method of staining.

Motility.—The typical bacillus coli communis is described as a motile organism. Is it essential that each organism isolated should exhibit motility and if it does not are we to reject it as not being a true bacillus coli?

My experience of motility is that its exhibition by different races of bacillus coli is very variable. Among organisms otherwise giving in every respect all the characters of the typical bacillus coli some will be found to be sluggishly motile, some very actively motile, others exhibiting no motility at all. The methods used to examine for motility were either, or both, of the following: examination in hanging-drop preparation of a not greater than 24 hours' old broth culture or examination of young gelatin-slope cultures (after less than 24 hours' incubation at from 20° to 22° C.) in a hanging drop of sterile broth. Occasionally an organism non-motile by one method would be distinctly motile by the other. How far is this motility or non-motility a stable character and how far is it a question of environment? Gilbert and Lion divided the varieties of bacillus coli found in the stools of 60 healthy men into two groups: (1) motile and (2) non-motile. Other observers describe their results as variable.

Motility is a fundamental character and too important to be used as a mere variety differentiator. It must, I think, be accepted that all true bacilli coli are motile. The *exhibition* of motility is, on the other hand, largely a question of environment. If this is so the apparently non-motile bacilli coli should all be made to exhibit motility under suitable environment. I have made a considerable number of experiments in this direction from time to time and have in almost all cases been able definitely to show true motility in organisms otherwise quite typical but, when isolated, non-motile, sometimes by prolonged growth on artificial media, at others by varying the method of examination. My conclusions are that all true bacilli coli are motile but that when isolated many of them do not exhibit any motility. These on prolonged subcultivation or other appropriate means can usually be made to show motility. From this it follows that as a practical test for the diagnosis of this organism the presence of motility when isolated is of little or no value.

Liquefaction of gelatin.—It is usually accepted that the true bacillus coli does not liquefy gelatin, although some observers have described liquefying forms as members of this group. All liquefiers of gelatin should be excluded as not true organisms in my opinion. The cultivations should be kept in the incubator for at least two weeks.

Gelatin slope growth.—Rapid growth should take place at from 20° to 22° C., visible within 24 hours, and yielding within 48 hours a bluish, smooth, translucent growth which remains unaltered after two weeks' incubation. Slight variations are sometimes met with, the growth being in some races thicker and whiter than the typical bluish translucent variety. The variations in my experience are but slight and this is a most valuable culture test.

Gelatin surface colonies.—My experience of gelatin surface colonies is that while the majority are perfectly typical there are other types which are not uncommon and which are given by organisms typical in all other respects. The typical colonies are well developed after from 40 to 48 hours in the cool incubator, and under a low power of the microscope appear as flat colourless or pale brown colonies with an irregular outline and wavy indented margin. Over the surface and extending in from the margin, and particularly observable away from the centre, are a number of wavy lines (marmoration). Sometimes the colonies are uniformly granular and without these lines.

Next most frequently met with after the above (type A) is what I have called type B. These colonies are to the naked eye somewhat raised and circular, while they are whiter and more opaque than type A and generally somewhat smaller. Under a low power they appear as well-defined colonies, nearly circular, and with well-defined slightly wavy borders. They are brown, uniformly and finely granular all over, and without wavy lines. The colonies from bacillus coli when growing in unfavourable circumstances are sometimes still smaller and perfectly circular, with quite smooth well-defined margins. Under a low power they are brown and uniformly granular (type C). A small number of colonies of this bacillus are when isolated quite abnormal. These characters are independent of whether the organism is perfectly typical in other ways or slightly removed from the typical.[1]

These variations in the types of the colonies are mainly no doubt due to immediate environment, but also partly to acquired characters and the influence of more remote environment. As a rule, an organism giving atypical colonies can be induced by artificial cultivation subsequently to exhibit typical colonies. For practical purposes it will be found that frequently, indeed usually, the colonies are almost or quite typical particularly when the organism has been isolated from drinking water, yet the fact that they are not typical does not exclude them of necessity from being true bacilli coli.

Agar slope.—This is an abundant rapid growth but of no diagnostic significance. The uniform turbidity produced in *broth* is also of no diagnostic significance since it is given by so many organisms.

Indol production.—This is one of the classical characters of the bacillus coli. It may be shown in broth (sugar free) but is most reliably demonstrated in peptone-water cultures

Table I.

Source.	Number of bacillus coli examined.	Indol produced.	No indol produced.	Percentage giving indol reaction.
Water-supplies	135	127	8	94
Human excreta (healthy)	19	18	1	95
" " (infantile diarrhœa)	10	10	0	100
Animal excreta	18	14	4	78
Sewage	5	5	0	100
Soil	12	12	0	100
Tidal river mud	38	34	4	89
Sea water and tidal river water	13	13	0	100
Shell-fish (all but one from cockles)	22	16	6	73
Flies	18	17	1	94
Totals	290	266	24	91·7

---

[1] For further details see paper by the writer in the Journal of Pathology and Bacteriology, March, 1904.

(from 7 to 10 days old). Is this an essential character, and is an organism typical in every other way, but which does not produce indol, to be considered not a true bacillus coli communis?

The results of a number of bacilli coli recently worked out by me and isolated from various sources are given as regards indol production in Table I. In this table are only enumerated organisms [illegible] other characters, such as acid [illegible] lactose and glucose, coagulati[illegible]ral red reaction, typical growth on gelatin slope and without any liquefaction of the medium. The formation of indol was tested for in peptone-water (from 7 to 10 days' incubation at 37° C.) in every case, except for a few of the bacilli coli isolated from drinking waters, which were tested in ordinary broth. In these if a negative result was obtained with broth a further examination was made in peptone water cultivations.

From Table I. it will be seen that 8·3 per cent. of bacillus coli, otherwise typical, gave no indol when isolated. The percentage of negative results varied considerably with the sources of the organisms, being lowest (73 per cent.) for bacillus coli isolated from cockles. Are these 24 organisms, otherwise quite typical, to be rejected from the fold of the elect bacillus coli? It seems to me that the question turns upon the variability of this character.

I have from time to time re-tested a number of the above organisms which, when first isolated, showed no indol production, and in most of them I have been able to demonstrate subsequently true indol production in peptone-water cultivations after one week's growth at 37° C. In every case the method of indol testing has been to add from 0·5 to 1·0 cubic centimetre of 0·02 per cent. potassium nitrite solution and then six drops of pure sulphuric acid. The tubes were then either left for one hour at room temperatures, or for my later work kept for ten minutes at about 60° C. in a water bath.

I believe that under unfavourable conditions the power of indol production may be lost, to be subsequently often reacquired if the conditions are more suitable. Many workers, however, do not recognise the possible variability of this character and Horrocks[2] states: "I have never been able by any treatment whatsoever to cause an organism, which when first isolated from *dejecta* showed no signs of indol formation, to assume that faculty." The italics are mine. That may well be so for dejecta but I believe that with less favourable environment this property may be lost.

For practical working purposes I would only reject an organism typical in all respects, except that no indol was formed, as not a true bacillus coli when after several weeks' growth in the laboratory and again testing in fresh peptone water it still failed to produce indol. That is, I should reject it as not having the full significance as an indicator of fairly recent excretal contamination which attaches to typical bacilli coli.

Production of acid.—Production of acid in litmus milk or in litmus whey is a constantly present character of bacillus coli communis. The formation of acid must be permanent since some allied organisms (bacillus enteritidis group) are [illegible] hundreds of bacilli coli isolated I have never found this character variable or absent.

Milk coagulation.—This is due in practically all cases to the formation of acid and in my experience commences when 32 per cent. of acid has been produced and is usually complete when about, or rather under, 40 per cent. has been produced.[3] It usually takes place within three days but the tubes should be incubated for at least two weeks at 37° C. before being rejected. Is this an essential character? Out of 250 bacilli coli isolated from different sources and which were typical as regards all the ordinary characters of this organism (this does not include gelatin surface colony characters or the possession of motility) only ten failed to coagulate milk. These ten all pr[illegible] in milk but failed to clot it even [illegible] for as long as one month. Is this [illegible] My experience is that it is st[illegible] variable. I have made extended [illegible] non-coagulating bacilli to coagulate milk by artificial means but without success. The methods used included growing in milk containing calcium chloride, soluble phosphates, prolonged artificial incubation in milk, frequent subcultivations from one milk tube to another, &c., but none induced clotting. I do not think these experiments need be detailed further.

In a few cases I have found no coagulation in the first milk tube and subsequent clotting when at once reinoculated into fresh milk tubes, but these are not included in the above and were probably due to some peculiarity in the milk media tubes. For *practical* purposes, in my opinion, organisms which do not coagulate milk within 14 days should not be considered as true bacilli coli. On the other hand, I think it highly probable that these [illegible] but typical in all other [illegible] bacilli coli but have los[illegible] sufficient quantity of acid to coagulate the milk, presumably from adverse environment. Taking this view, I would provisionally regard them as of less significance than quite typical bacilli coli, since the fæcal contamination may have been more remote, but if they can be shown to be prevalent in large numbers in excrement and absent, or relatively absent, in unbefouled materials, then, of course, they would have a significance of their own. The origin of these ten organisms does not negative this view, since one was derived from "made soil," one from horse manure, and one from tidal river mud containing at the same time perfectly typical bacillus coli communis, while the remaining seven were from water-supplies in all of which the quite typical organism was isolated from time to time, frequently at the same time. It is noteworthy that out of the large number of different sources of water-supply examined two should have been derived from the same source (one six months later than the other) and two from another source (but with a year's interval). Of course organisms only superficially resembling the bacillus coli but differing in several characters as well as non-coagulation of milk are not infrequently met with but these are not included in the above.

[illegible] distinctive characteristic.

Lactose fermentation.—This is, perhaps, the most important differentiating character. All true bacilli coli ferment lactose with production of acid and gas. Extended experience has convinced me of its fundamental importance and I would reject all organisms as not true bacillus coli communis if they did not ferment lactose with production of acid and gas. In this way a number of rather closely allied organisms can be excluded, which no doubt have a significance and importance of their own, but which cannot be classed as having the same significance as typical bacillus coli. In this connexion a number of organisms which I have isolated from time to time, and which all have the common property that they ferment lactose much less than the typical organism, are of interest. The characters of 12 such organisms fairly recently isolated and from a variety of sources are given in Table II.

All lactose fermentations were tested in Durham tubes in media consisting of 1 per cent. lactose and 1 per cent. peptone in water tinted blue with litmus solution. When the amount of gas produced is mentioned it is to be understood as being the height of the gas in the inner tube. The tubes were of approximately the same diameter but the [illegible]ery rough one, [illegible] as true bacillus [illegible]ther points from [illegible] No. 1 when first [illegible] after ten days' [illegible] actively motile. [illegible]ose-peptone solution but only two or three bubbles of gas. After being kept in the laboratory a week or two it produced [illegible]n inch of gas in the inner tube after [illegible]ation. Kept from four to five months [illegible] and again tested in lactose-peptone [illegible]roduced gas—i.e., two-thirds of an inch in two days. Also with fresh litmus milk the milk was coagulated after six days' incubation. No. 2 was typical in every way except the slight production of gas in the lactose tube. Re-examined after six months and after rejuvenation

---

[illegible]

TABLE II.—SHOWING THE CHARACTERS OF THE ORGANISMS WHEN ISOLATED.

No. of organism.	Source.	Gelatin surface colonies.	Gelatin slope.	Liquefaction of gelatin (2 weeks).	Litmus milk.			Indol production.	Neutral red reaction.	Glucose fermentation.	Motility.	Lactose fermentation.			Starch fermentation.	Saccharose fermentation.	Dulcitol fermentation.	Raffinose fermentation.
					Acid.	Coagulation.	Time to coagulate.					If acid.	If gas.	Amount of gas (1 week).				
1	River mud after being kept in laboratory three weeks.	Quite typical.	Bluish trans-lucent growth.	−	+	+	10 days.	+	+	+	+ Very active.	+	2-3 bubbles only (1 week).		−	+	−	Very little
2	River mud.	"	"	−	+	+	2 days.	+	+	+	+ Active.	+	+	¼ inch.	−	−	−	
3	River water.	Not quite typical.	"	−	+	+	4 days.	+	−	+	−	+	+	Very slow; ⅓ inch.	−	+	−	
4	Cockles.	Quite typical.	"	−	+	+	10 days.	+	−	+	−	+	+	Slow; ¼ inch.	−			
5	Healthy stool.	Not examined.	"	−	+	+	2 days.	+	−	+	−	+	+	¼ inch.	−	+	−	+
6	River mud after being kept one month in laboratory.	Atypical.	"	−	+	+	6 days.	+	+	+	+ Very active	+	−	−	−	+ +	−	+
7	River mud one week after being collected.	Quite typical.	"	−	+	+	2 days.	−	+	+	+ Active.	+	1 bubble.		−	+ Little.	+	−
8	Stool, child, case of epidemic diarrhœa.	"	"	−	+	+	4 days.	+	+	+	−	+	+	¼ inch.	−	−	+	−
9	Fly.	Typical.	"	−	+	+	12 days.	+	+	+	+ Active	+	1 bubble.		−	+	+	Acid only
10	River mud, same as No. 7 but when collected.	Quite typical.	"	−	+	−	2 weeks.	+	−	−	−	+	+	Slow; ⅓ inch.	−	+		
11	Fly.	More circumscribed and smaller than typical.	"	−	+	+	7 days.	+	Partial.	+	+ Very active.	+	2 bubbles.		−	−	−	−
12	Tidal mud kept in tank in laboratory.	Typical.	"	−	+	+	2 days.	Traces	+	+	+ Slight.	+	1 bubble only.		−	+	+	+

by growing first in broth, then on gelatin plate, then in litmus milk, it gave the same results. Here the slow and little lactose fermentation was constant. In the same way No. 3 when isolated gave no neutral red reaction and the gelatin surface colonies were not perfectly typical. After some months in the laboratory, the gelatin colonies were quite typical but no neutral red reaction as before. The repetition of the lactose fermentation was also very similar in both, yielding after four days' incubation only acid and one bubble of gas, but after six days as much as one inch of gas in the inner tube. For No. 4 apart from slow and slight production of gas in lactose-peptone water, milk was coagulated only on the tenth day (repeated with same result on several occasions) and no neutral red reaction was obtained. It then died out, so that fresh examinations could not be made. No. 5 was very similar except that it clotted milk rapidly. Unlike most bacilli coli it only fermented mannite slowly and not well. It died out so could not be re-examined. No. 6 is included here because at first sight it belongs to this group. It is, I believe, however, quite a different organism and mainly characterised by its fermenting saccharose and mannite with extreme production of gas. Maltose and galactose, as well as glucose, are all rapidly fermented. Repeated growth in fresh lactose-peptone tubes gave always acid, but never more than one bubble of gas. The gelatin surface colonies, examined on several occasions and after long intervals of time, never became typical, being always smaller and less inclined to spread than the common type of bacillus coli. This organism is certainly not a bacillus coli. No. 7 when isolated produced no indol and only gave one bubble of gas in the lactose tube. Re-examined one month later and after being kept on artificial media for that time it gave the same results with the lactose tube and still gave no indol. I hope to re-examine again after some months' growth in the laboratory. No. 8 when isolated fermented lactose with but little production of gas. Re-examined two months after isolation it fermented lactose still slowly but with production of more gas (from one-third to one-half of an inch). No. 9 was re-examined two months after isolation, when one-fifth of an inch of gas was produced in the inner tube of the lactose medium after three days' incubation. When isolated, milk was coagulated in 12 days but two months later in from five to six days. With No. 10, when isolated, milk was not coagulated in two weeks but on inoculation from this into fresh litmus milk tubes gave complete clotting in three days, so this may have been due to some abnormal condition of the first milk tube. Fresh lactose inoculations after six weeks in the laboratory gave now typical and rapid gas production. When isolated no gas was formed in neutral red glucose agar shake preparation and no neutral red reaction. This was repeated with exactly similar results on several occasions soon after isolation. After six weeks in the laboratory there was fairly abundant gas production in freshly made shake preparations but still no neutral red reaction. The latter was also absent in neutral red broth cultures. After two months on a gelatin slope in the laboratory a complete neutral red reaction was easily obtained with No. 11, but the lactose fermentation was still but slightly marked as regards the production of gas (one-quarter of an inch in five days). No. 12 has not as yet been re-examined, except that the lactose fermentation results have been repeated several times with identical results and as recorded.

These organisms have been described in considerable detail because they, in part at least, illustrate, I believe, the effects of unfavourable environment. Excluding No. 6, I believe that the others are true bacilli coli altered by environment. No less than five were from mud from tidal waters kept for considerable periods in the laboratory. Under laboratory conditions, with abundant nutriment, in most cases some return to the normal was witnessed and with further investigation would probably be still more pronounced. Their practical significance is, however, debateable, since it may be argued that even if they are altered bacilli coli they do not point to recent pollution. They are not infrequently met with but provisionally I do not rely on, or consider, them as indicators of *recent* pollution, *Saccharose fermentation.*—All workers are in accord that this cannot be considered an essential character of bacillus coli. Escherich's bacillus coli communis does not ferment saccharose. Some typical bacilli coli, as usually defined, ferment cane sugar; others, probably the majority, do not. Some [illegible] fermentation of [illegible]

Star[illegible] does not ferment starch. Organisms are occasionally met with which resemble the bacillus coli closely but which ferment starch with the production of acid and gas. Apart from their gelatin surface colonies which are usually more compact, they may be suspected by the fact that their gelatin surface growth is thicker and whiter than the typical appearance. They are non-motile. I have isolated such organisms from as little as $\frac{1}{1000}$th of a cubic centimetre of sewage, but in my experience they are not abundant in sewage or excreta. I have not tested their growth on potato but, as a practical measure, if an organism gives a whiter and thicker growth on a gelatin slope than the typical appearance, it is advisable to test if it ferments starch (e.g., 1 per cent. starch peptone litmus water). Lactose and glucose are fermented, milk is acidified and coagulated, and indol is produced. Of two such organisms recently isolated one fermented saccharose, the other did not.

In regard to the fermentation of maltose, galactose, lævulose, mannitol, glycerine, &c., I have not found that specially testing for such fermentation has up to the present yielded results worth the trouble or of value in the differentiation of this organism.

Potato.—In my opinion to grow this organism on potato serves no useful purposes, apart from the possible differentiation of a bacillus lactis aerogenes organism, and can be omitted without loss. In the same way the reduction of *nitrates to nitrites is caused by bacillus coli, but this* property is one common to so many other bacteria that it is valueless as a routine test.

Neutral red reaction.—This is a very useful test but the reaction is one given by a n[illegible] I have found the reaction to b[illegible] variable and from time to time [illegible] typical in all other ways which when isolated gave no neutral red reaction (in glucose neutral-red agar shake preparations) but which after a short period of artificial subcultivation in the laboratory gave the reaction. If no neutral red reaction is obtained usually the organism isolated also deviates in one or other property from the typical bacillus coli.

Pathogenicity.—Most bacteriologists, at least in this country, have not found that the pathogenicity of isolated bacillus coli is of any help in determining the potency for evil of the material (soil, water, &c.) under investigation. As a routine test it is not to be commended.

In regard to the different methods for isolating and indicating the presence of bacillus coli such as MacConkey's medium, neutral red, &c., none of them can be relied upon to indicate by themselves with certainty the presence of bacillus coli. They are invaluable as an aid to isolation but in every case the bacterium must be separated in pure culture and its characters worked out. This is apparently accepted by all workers at this subject. While it is of advantage to employ as large a number of tests as possible, yet for routine work, when the labour involved is considerable, it becomes of great practical importance to have a minimum number of tests to use and yet tests which will give a sufficiently reliable means of indicating if any organism is a true bacillus coli or not. The work done on the characters of this organism is so large and on some points the unanimity is so considerable that it should not be difficult to fix a minimum number of tests to do and a minimum number of positive results to obtain.

The *report of the committee appointed at the 1903 Congress* of the Royal Institute of Public Health to consider [illegible] although personally I have foun[illegible] not exhibited, on isolation, by bacillus coli quite typical in [illegible] other respects. Put another way, I believe it would be [illegible] *great benefit to public health bacteriology if bacteriologi*[illegible] would agree as to the essential subcultivations to perform. *The six tests of the committee, in my opinion, might be even* reduced to five, omitting growth on agar slope, and the following would give all the essential tests—i.e., (*a*) growth on gelatin slope; (*b*) litmus milk at 37° C.; (*c*) lactose-peptone litmus solution (in a Durham tube); (*d*) peptone water; and (*e*) glucose neutral red agar shake preparation. Growth in glucose-peptone litmus solution in a Durham tube and another in neutral red broth can be substituted for this. From this the following results should be recorded. 1. Morphology and motility. These can be conveniently investigated from (*a*)—e.g., a hanging-drop preparation in broth after 20 hours' incubation. I do not think it essential to stain by Gram's method as a routine practice. 2. Translucent non-corrugated appearance on gelatin slope. 3. Non-liquefaction of the gelatin (two weeks). 4. Permanent—i.e., two weeks—acid production in litmus milk. 5. Milk clotting (within two weeks). 6. Lactose fermentation with the production of acid and gas. 7. Glucose fermentation (production of gas in glucose neutral red agar shake preparation). 8. Neutral red reaction; fluorescence and reduction to yellow. 9. Production of indol in (seven to ten days at 37° C.) peptone water. I believe that these tests are for all practical purposes quite sufficient reliably to indicate the bacilli coli which indicate excretal contamination. They require only five tubes of media and they are quickly performed.

I would suggest the use of the term *excretal* bacillus coli, and that an organism giving all these characters (whether motile or not) *should be definitely implied when the term excretal bacillus coli* is used. My experience is that the majority of organisms isolated in routine work as suspected bacillus coli from fluids such as neutral red broth or MacConkey's medium will give characteristic results with all these media. Bacillus-coli-like organisms, however, do not, as every worker *at this subject is well aware, always yield all positive* results with the above tests, and one or other of them may not be obtained. From the literature of the subject two rather opposite views seem to be held. On the one hand, the advocates of the one view draw the line strictly and say that an organism which does not give all the above, and perhaps *other* tests also, is *not* a bacillus coli indicating excretal contamination; on the other hand, others include bacteria lacking one or more of the above—e.g., milk clotting, indol production—and still include as bacillus coli indicating excretal contamination. The first view may, I believe, exclude organisms which are true indicators of excretal contamination but which have lost one or other of their original characters from unfavourable environment; the latter view is still less satisfactory since it may undoubtedly include organisms found in unpolluted sources and which do not indicate excretal pollution. The key to the question appears to turn upon the variability of these characters and from that point of view I have carried out a large number of experiments during the past three years. My personal opinion in the matter is that the following characters should be considered [illegible] motility is exhibited or not. Indol reaction is a most important test but I do not regard it as so quite essential as the above and should only reject when no indol could be obtained after laboratory subcultivation for some time and then fresh tests made. The neutral red reaction is also of great im[illegible] that its [illegible]

I am [illegible] ot give all the above tests (e.g., organisms which fail to clot milk otherwise positive in their characters) are of necessity not indicators of fæcal contamination. They very possibly may be but the position in regard to them is not so sound as for those which I have ventured to call excretal bacilli coli—meaning by the term not that they are the only bacilli coli [illegible]d in excreta, for they are not, but that they are trust[illegible]thy indicators of excretal contamination. For this group [illegible] do know that they are abundant in fæces and in sewage, [illegible] we do know that they are absent or relatively absent [illegible] mud, and soil not recently polluted. [illegible] a strong one. For the less typical [illegible]gnificance of their own but it has not been so accurately gauged and so more care is required in drawing conclusions. I do not believe, however, that such organisms can be passed by as of no significance.

---

[3] See Journal of State Medicine August, 1904.

The main object of this paper has been to indicate the tests which, in my opinion, are the least which should be done but which yield all the evidence necessary to enable us to gauge whether or no the organism found is one not met with in pure sources but found abundantly in contaminated sources and to urge the need for uniformity.[4]

It must not be supposed, however, that all organisms marked off by the above tests are identical even if the differences of gelatin surface colonies, presence or absence of motility, be neglected. If such organisms be further examined to determine their power of fermenting different sugars and allied bodies it will be found that many further divisions can be made. Thus, some will ferment saccharose, others not, some dulcitol (dulcite), others not, &c.

I have been for some time now engaged in work having for its object the differentiation of bacilli coli from different sources, in particular from human and from animal sources, and for this purpose have made use of different sugars. The details which follow can only be considered as a preliminary note. Dealing only with bacilli coli which exhibit all the characters described above — morphology, characteristic gelatin-slope growth, no liquefaction of gelatin, fermentation of glucose and lactose, acid production, milk clotting, neutral red reaction, indol production,—these can be separated into quite a number of varieties and, as far as I have re-tested their characters, stable varieties.

The following classification of organisms isolated has no significance other than practical convenience and the dulcitol fermentation might equally well be used as a group differentiator before saccharose.

Group I.—Saccharose fermenters. Sub-group (*a*) dulcitol fermented and sub-group (*b*) dulcitol not fermented. A large number of both sub-groups were met with. They could be further differentiated by their action on other substances. Thus some fermented salicin; others did not break up this substance. Some split up glycerine with gas production, others had no obvious action. So far all the bacilli coli of this group which fermented saccharose have fermented raffinose also. I have not found the converse true, however, since all raffinose fermenters do not also ferment saccharose.

Group II.—Dulcitol fermenters but not saccharose. Sub-group (*a*) raffinose fermented; and sub-group (*b*) raffinose not fermented. A large number of organisms belonging to both sub-groups were isolated and could again be further differentiated by salicin and other substances.

Group III.—Maltose fermenters but not saccharose or dulcitol.

These have been rather less numerous than either Groups I. or II. in the results so far obtained. Most have fermented salicin but a few not. The majority have not fermented raffinose but a few have to a slight extent. In this way a very considerable differentiation into groups and sub-groups can be made out but at present I am not in a position to say whether there is any trustworthy differential distribution of these different sub-groups in excreta from different sources or any difference in their relative significance. That these differences exist indicates, however, the complexity of the subject.

Colchester.

A CASE OF TYPHOID FEVER PRESENTING SOME UNUSUAL FEATURES.

BY KENNETH ANDERSON, M.B. LOND., M.R.C.S. ENG., L.R.C.P. LOND.,

LATE HOUSE SURGEON, WESTON SUPER MARE HOSPITAL.

ALTHOUGH the symptomatology of typhoid fever is notoriously subject to the greatest variations the following case seems to me to have an unusual share of atypical features and on that account may be of interest to the profession.

A woman, aged 30 years, was admitted into the Weston-super-Mare Hospital on March 6th, 1903, for severe pain in the left loin. On March 1st she had had a "shivering fit" followed by pain. Previously to this she had felt quite well. During the next few days she was feverish and the pain was more or less continuous. She had noticed nothing unusual in her urine. Dr. G. H. Temple, who had been called in and found her surroundings unsuitable, advised her removal to the hospital. She was admitted as a surgical case under the care of Dr. G. F. Rossiter. On admission the temperature was 101·4° F., the pulse was 104, and the respirations were 26. The patient was not in actual pain. The abdomen was moving fairly well and was not distended; it was supple in most parts except in the left hypochondrium, which was rigid and extremely tender, and there was slight rigidity of the recti; palpation in the left loin caused much pain and the skin over the region of the kidney was hyperæsthetic. The patient had been sick and was constipated; the tongue was clean but rather dry; a few sibilant rhonchi were heard over both upper lobes, more especially on the right side. The urine was acid and contained a small amount of pus; the patient afterwards told us that she had had cystitis two years ago. On the 8th, at 10 P.M., the temperature was 103·2°; tenderness in the loin was less; the bowels were relieved by calomel. The temperature gradually fell during the next few days and the pain and tenderness in the loin entirely disappeared; the recti, however, remained rigid. There was now some impaired resonance at the left base, with slight harshness of the expiratory sound; rhonchi were still heard over the right upper lobe. The pulse was soft but not dicrotic and during this period of pyrexia never exceeded 100 after the 10th. The temperature oscillated irregularly from the 11th to the 15th and was normal on the evening of the latter day; the tongue was moister and the patient now felt fairly well. The only treatment adopted beyond purgatives was the application of turpentine fomentations to the abdomen. The case was regarded by Dr. Rossiter and also by Dr. R. Roxburgh, who was thenceforth in charge of it as a medical case, as one of perinephritic inflammation which had subsided. The question of renal tuberculosis was considered, but the specimen of urine submitted to the Clinical Research Association was free from tubercle bacilli.

The patient now seemed to be on the road to recovery; the temperature kept subnormal for four days; the diet was increased gradually, but on the evening of the fifth day of apyrexia (the 20th) the temperature suddenly rose to 102·8°, a rub was heard at the right base, and an occasional crepitation in the lungs. The temperature became distinctly oscillating but seldom reached normal even in the mornings, and in the evenings was generally 102° or 103°; the pulse kept about 100 and the respirations 24. A hæmorrhagic vaginal discharge, which was at first taken to be a menstrual period, began on March 21st, the period being a month overdue. From the 28th to the 31st the fever was much less and the patient seemed better; during this time there was no pain or abdominal tenderness but the recti were always rigid. Sibilant rhonchi persisted at the right apex but otherwise there were no definite physical signs pointing to pulmonary disease. The urine still contained a little pus. By the evening of the 31st the temperature was 101·2°; it kept at this level next day, the pulse being 96; the tongue was dry and slightly furred. The patient was looking ill and rather lethargic. On April 2nd a report of Widal's reaction given by the patient's blood was received from the Clinical Research Association. The blood gave a good reaction with dilutions 1 in 10 and 1 in 25, and a slight reaction with dilution 1 in 50. There being no history of a previous attack of typhoid fever this was regarded as conclusive. That night her temperature reached 104·8°, it fell quickly but at 4 A.M. she had a rigor and the temperature being 104° she was sponged with water at 80°. For the next four days the pyrexia continued without marked diurnal variations and she was twice sponged on the temperature reaching 103°. The pulse remained steady, about 96 to 100 She took milk well and enemata were given daily to relieve the bowels, the motions now being typically "pea-soupy." The liver dulness reached an inch below the costal margin; the spleen could not be felt but the splenic dulness extended nearly to the nipple line; the recti muscles remained rigid. The vaginal discharge, which had continued since March 21st, now became very foul, and boric douches were given night and morning. On April 7th the temperature ranged a good deal lower, the maximum being 100·2°. On the 8th while micturating she passed, without pain, a small pear-shaped body per *vaginam*; this was very foul and consisted of a membranous bag containing fibrous tissue and blood clot and was considered to be a carneous mole. The os uteri was patulous, admitting the tip of the index finger (the patient was a nullipara), but the abdominal rigidity prevented the uterus being examined bimanually. The vaginal discharge was much increased for some hours after this and soon became sweeter; ergot was administered. The temperature fell to normal, and remained so, on the morning of the 10th, and the discharge ceased on the 11th. As constipation was still very troublesome half-grain doses of calomel were given thrice daily. A few typical spots were now seen for the first time, mostly on the back. For the next three days the temperature remained subnormal and the pulse improved in quality and at times was very slow (60). On the 15th, however, the temperature went steadily up to 102° and remained at, or above, this level till the evening of the 18th, during which time she was sponged six times. The pulse now became rapid (120 or more) and very feeble, the heart sounds were short and weak, and the patient seemed desperately ill. Brandy was increased to half an ounce every two hours and a mixture containing seven minims of tincture of digitalis and three minims of liquor strychninæ was given every four hours, together with half a drachm of aromatic spirit of ammonia. The rhonchi persisted in the right lung and the liver enlargement was unaltered. The bowels, under the influence of small doses of calomel, were now acting of themselves. On April 19th the temperature became normal, the pulse-rate fell to 88 and its quality improved, the heart sounds also becoming more distinct. The digitalis had to be omitted owing to vomiting which it caused. From the 22nd to the 24th there was another slight recrudescence of fever but it caused no trouble and from that time the temperature remained subnormal. About this period the gums became sore and spongy; this was attributed to the calomel, which was stopped, and the condition was treated with mouth washes of potassium chlorate and alum, and soon passed off. Convalescence was uneventful; solid food was allowed on the tenth day of apyrexia and the patient regained her strength wonderfully soon and was discharged to the West of England Sanatorium on May 25th.

---

[4] Since writing this paper in [illegible] *contribution to the subject by Dr.* [illegible] the report of the medical officer to [illegible] This should be consulted for a [illegible] characters of bacillus coli from normal stools.

The course of the temperature was as follows. On admission on March 6th it was 101·4°. On the 8th in the morning it was 100·4° and in the evening 103°. After this date until the 15th the temperature fell on the whole, although it oscillated, and by the evening of the 15th it was 98·6°. It remained subnormal until the evening of the 20th when it shot up to 102·8°. On the evening of the 21st the vaginal discharge began. Between this date and April 2nd the temperature oscillated but always kept above normal, the evening temperature being between 101° and 103°. On the 27th it reached 103·2°, after which more oscillations occurred until the evening of April 2nd, when the reading was 104·8°. On the 8th the carneous mole came away and on the morning of the 10th the reading was 97°. The vaginal discharge ceased on the following day and the temperature remained subnormal until the evening of the 15th, when it rose to 102·6°. Thence it rapidly fell, except for an evening rise on the 17th to 103·2°, until on the evening of the 19th the reading was 97°. From the 22nd to the 24th there was a slight recrudescence of fever, but from the last-named date the temperature was either normal or subnormal until the patient was discharged.

The chief points of interest in the case seem to be as follows:—

1. *The difficulty in diagnosis.*—The onset with a rigor and acute localised abdominal pain seemed to point to some nephritic or perinephritic suppuration and the presence of pus in the urine was at first regarded as confirmatory of this till the history of cystitis was obtained. The rapid amelioration of the pain and tenderness at the end of a week, however, was a contra-indication, while the temperature, the pyuria, and the pulmonary signs suggested the possibility of tuberculous mischief somewhere, but the character of the pyrexia was hardly that of tubercle and the signs in the lungs were not conclusive. The persistence of sibilant rhonchi over the right upper lobe throughout the whole illness is interesting and their presence led us to think of typhoid fever fairly early in the case, though it was much too slender a basis for a diagnosis The absence of any cardiac murmurs, of sweats, and of hæmaturia was against infective endocarditis with embolism in the kidney. The value of Widal's reaction in these cases is clearly proved, confirmed as it was later by the spots, the enlarged spleen, and the character of the stools. The absence throughout of cerebral symptoms, even such as headache, of dicrotism in the pulse, of any marked tympanites and, for a time, of spots, which were constantly watched for but which only appeared late in the case and were limited to about half a dozen on the back, all these negative features are worthy of notice.

2. *The course of the disease.*—Assuming that the onset was really on March 1st, and the patient said she felt quite well up to then, the original fever was short, for the temperature was normal on the evening of the fifteenth day and remained so for some time. There were then three relapses, separated by short apyrexial intervals, and a fourth slight recrudescence of fever later; each relapse, however, was of short duration. In the second relapse the spots appeared for the first time. During the second and third relapses the patient was much more seriously ill than she was during the initial fever and in the latter most grave symptoms of cardiac failure occurred.

3. *The occurrence of abortion.*—We had no idea that the patient was pregnant until after the discharge of the carneous mole. A previous vaginal examination had not detected the slight enlargement of the uterus which must have been present, bimanual examination being hindered by the rigid recti. According to Osler, 65 per cent. of pregnant women abort during an attack of enteric fever. No doubt the foul condition of the uterine contents was a factor in the pyrexia of the second relapse.

4. *Other points of interest* are—1. The inability to continue the administration of digitalis by the mouth, owing to gastric irritation so produced. Fortunately, the cardiac condition improved at this time; had it not done so we were prepared to give the drug per rectum. 2. The occurrence of stomatitis after the administration of mercury in small doses for about three weeks. 3. The enlargement of the liver, which was present when the patient left the hospital. 4. The absence of any sequelæ. The case is a good example of the protean variability with which enteric fever may present itself and a reminder that in all imperfectly explained pyrexias the idea of typhoid fever should be ever present in the practitioner's mind.

I am indebted to Dr. Roxburgh, honorary physician to the hospital, for permission to publish this case.

Banwell, Somerset.

HYDATID CYST SIMULATING SUBPHRENIC ABSCESS.

By J. PORTER PARKINSON, M.D. Lond.,
M.R.C.P. Lond.,

PHYSICIAN TO THE LONDON TEMPERANCE HOSPITAL AND TO THE NORTH-EASTERN HOSPITAL FOR CHILDREN.

THE following case presents certain points of interest from the position of the cyst which was that of the most usual variety of subphrenic abscess, and also from the gastric symptoms which were no doubt produced by the displacement of the stomach.

A woman, aged 27 years, had suffered for two years from weakness and malaise, with frequent pains in the region of the left hypochondrium. These pains, attributed to indigestion, were often accompanied by vomiting and also by attacks of faintness. The pains appeared to have relation to the taking of food and at times were so severe and long-continued that she remained in bed for days at a time. There was no history of the passage of blood by the mouth or the bowel. About nine months before I saw her a tumour had been discovered in the abdomen and was said to be an enlarged spleen.

When I was called to see her in consultation with her medical attendant she was thin but not emaciated. The tongue was slightly furred and the bowels were very constipated. There was some bulging of the lower part of the chest in front on the left side and above this the cardiac impulse could be seen in the third intercostal space. A swelling with a rounded limit below could be felt extending from beneath the costal margin on the left side for a distance of three fingers' breadth; it was smooth, tense, and felt semi-solid. It extended from a point about one and a half inches to the right of the middle line to the left mid-axillary region, ascending beneath the costal margin at each extremity. The lower limits distinctly descended with a deep inspiration. It was dull all over except for a small portion beneath the ensiform cartilage, where it was moderately resonant, and the dulness was continued into the chest obliquely to join the cardiac dulness in front; so that almost the whole of the chest in front below the second rib cartilage was dull. The upper part of this was obviously due to the displacement upwards of the heart. Behind there was dulness on the left side of the chest as high as the angle of the scapula, bounded above by a curved line with its convexity upwards, descending towards the spine and towards the axillary region. It was noted that the upper limit of this dulness descended slightly with a deep inspiration. Over the dull area the vocal fremitus and resonance and breath sounds were absent. There were no other abnormal physical signs discovered in the chest or the abdomen. The liver appeared to be of normal size and there was no albuminuria. The spleen could not be made out. The blood examination showed slight anæmia but no leucocytosis. The temperature was normal.

It was obvious that we had to deal with a tumour below the left wing of the diaphragm which, unlike an enlarged spleen, exerted its chief pressure upwards. A subphrenic abscess seemed unlikely owing to the long duration, the absence of fever, and of any symptoms pointing to a previous perforation of the stomach, which is far the most common cause of subphrenic abscess on the left side. The possibility of the tumour being a pancreatic cyst was discussed, but these tumours do not, as a rule, move with respiration and they are situated more in the median line; the fæces also were normal in colour and consistency. A portion of the tumour was resonant, which is often the case in a pancreatic cyst owing to the stomach lying above it, but this was found at the operation to be due to the thin edge of the left lobe of the liver overlying the displaced stomach. Eventually by exclusion we arrived at a hydatid cyst as the most probable diagnosis.

Mr. Bilton Pollard arranged to perform abdominal section and discovered a hydatid cyst situated in the posterior part of the left lobe of the liver, pushing the anterior part of that lobe forwards. He evacuated five pints of a brownish fluid which microscopically contained red blood corpuscles, granular cells, crystals of cholesterin and débris. No hooklets were seen but a portion of the cyst wall showed the structure characteristic of hydatid. The cyst wall was stitched to the wall of the abdomen and drained. The patient's further progress was uneventful; she was out of bed in a month after the operation, though the fistula continued to discharge for some weeks longer. She finally recovered perfect health and all signs of the tumour have now disappeared.

At the operation it was seen that the stomach was displaced downwards and towards the mid-line and lay beneath the displaced left lobe of the liver, thus producing resonance over the right limit of the tumour.

It would appear that in this patient the ovum having perforated the stomach wall and the capsule of the liver developed in the nearest part of the liver which it reached and was not carried away in the portal circulation as usually is the case when it develops in the right lobe of the liver. Such a condition appears to happen in more than a solitary instance, for shortly after seeing the above case I saw at the necropsy of a patient who died from heart disease in the London Temperance Hospital a hydatid cyst of about the size of an orange in almost exactly the same situation, being adherent on the one hand to the posterior wall of the stomach near its cardiac end and also to the posterior part of the left lobe of the liver. This cyst was evidently in active growth and contained the usual hydatid contents, including hooklets, and if the patient had lived till it had grown to a larger size it would doubtless have produced similar symptoms and signs to those which I have mentioned.

Wimpole-street, W.

THE PROGNOSTIC VALUE OF THE DIAZO-REACTION IN ENTERIC FEVER.

BY J. D. ROLLESTON, M.A., M.D. OXON.,

ASSISTANT MEDICAL OFFICER AT THE GROVE FEVER HOSPITAL OF THE METROPOLITAN ASYLUMS BOARD, TOOTING.

THE prognostic value of the diazo-reaction in enteric fever was originally described by Ehrlich in 1882[1] and has subsequently been confirmed by several German, French, and American observers,[2] but hitherto has received little recognition in this country. The greater certainty attaching to Widal's test from a diagnostic standpoint has tended to throw Ehrlich's reaction into the shade, the use of the latter in prognosis being disregarded. The present paper, which is based on observations made on 65 cases of enteric fever in which the diazo-reaction was employed, offers confirmatory evidence of its prognostic value. A positive reaction in enteric fever is first obtained about the fourth day of the disease and tends to disappear by the end of the second or in the course of the third week. Its persistence beyond that period only occurs in severe cases and in spite of a fall of the temperature indicates that the infectious process is still active and that a recrudescence or relapse is imminent.

The following shows the diazo-reaction in 65 cases of enteric fever admitted at various stages of the disease: Cases admitted in the first week: 9 positive, none negative; second week, 24 positive, 9 negative; third week, 9 positive, 8 negative; fourth week, 2 positive, 2 negative; and fifth week, 1 positive, 1 negative. In 27 of these cases in which the test was employed throughout the disease the diazo-reaction became finally negative at the following dates: first week, 0; second week, 6; third week, 12; fourth week, 3; fifth week, 4; sixth week, 1; and seventh week, 1.

My own experience coincides with that of Oppenheim and Loeper who hold in opposition to Rivier[3] that an intense reaction is by no means the appanage of severe forms of the disease as it is found in the immense majority of cases in which the urine is examined during the first fortnight. It is only the persistence of a positive reaction that characterises a severe attack. Daily examination of the urine shows that the commencement of lysis occurs either simultaneously with the disappearance of a positive reaction or succeeds it by an interval of varying duration.[4] Thus out of 27 cases in 22 these two events occurred in the same week, in four cases lysis began in the week following, and in one instance there was an interval of 12 days between the two. Before the reaction disappears entirely there is usually a gradual diminution in its intensity, the successive grades being designated by Ehrlich R++, R+, R−, R−−, which correspond with shades of colour varying from a deep purple or carmine to a pale yellow. Not infrequently before the reaction becomes finally negative it may be occasionally positive. Generally speaking, so exceptional is it for the disappearance of the reaction not to be followed at a short interval by a decided fall in the temperature that a persistent pyrexia with a negative reaction indicates a secondary infection or impermeability of the kidney to the colouring matter, the latter, according to Ehrlich, constituting a grave sign. Thus, in seven of my cases in which aggravation of the general condition occurred after disappearance of the reaction three died from toxæmia, two from hæmorrhage, one from perforative peritonitis, and one from lobar pneumonia. Knowledge of the duration of the diazo-reaction is useful as a means of checking the history, which is often notoriously misleading, and in conjunction with the other symptoms helps one to arrive at a more accurate estimate of the length of the illness. As a rule there is a tendency to under-estimate the duration of the illness. A decidedly negative reaction (R−−) in an undoubted case of enteric fever indicates that the patient has in all probability been ill for at least 14 days. A positive reaction, on the other hand, in the absence of a relapse or recrudescence shows that the illness has lasted little more than a fortnight at the most.

The reappearance of the reaction after a period in which it has been negative indicates the imminence of a recrudescence of the disease if the temperature is not already settled or of a relapse if apyrexia has been established. On the other hand, a persistently negative reaction with a rise of temperature excludes the possibility of recrudescence or relapse. In certain cases of complications due to the specific bacillus the reaction hitherto negative may become positive again. Thus Lainois and Loeper record its presence in a case of typhoidal orchitis occurring in convalescence. It is, therefore, advisable to employ the test at frequent intervals for at least one month after the evening temperature has reached normal and not only to use the test throughout the febrile period. It is interesting to note that in diseases in which the reaction is rarely found—e.g., in tuberculosis, pneumonia, and diphtheria—a positive result is of still graver omen than in enteric fever (Ehrlich). In measles in which the reaction is as constant as in typhoid fever no prognostic value attaches to its presence or persistence.

[2] Escheri[illegible] No. 7, 1883. Krokiewicz [illegible] Michaelis: Deutsche [illegible] Traité de Médecine [illegible] typhoïde, 1899. Brannan: Twentieth Century Practice of Medicine, 1899. Oppenheim et Loeper: Gazette des Hôpitaux, May 25th, 1901.

[3] Thèse de Paris, 1898.

[4] Chantemesse (loc. cit.) says that the disappearance of the reaction may follow the fall of the temperature.

Summary.—(1) In all but severe attacks the diazo-reaction tends to disappear in the course of the second or third week, this disappearance shortly preceding, or coinciding with, the commencement of lysis; (2) its reappearance during or after the completion of lysis is a warning of recrudescence or relapse, or of complications directly due to the specific bacillus; [illegible] f the reaction associated [illegible] condition is of bad omen, [illegible] ction is a useful check to the history.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NON-TRAUMATIC CEREBRAL HÆMORRHAGE IN A CHILD, AGED TEN YEARS.

BY HUGH TAYLOR, M.A. CANTAB., M.A., M.D. DUB.

THE following brief note of an extensive cerebral hæmorrhage without any traumatic origin occurring at such an early age is, I have ventured to think, worth recording.

About 10 o'clock on the evening of Dec. 31st, 1904, a little girl, aged ten years, who had "never been really ill in her life" and who had been playing about all day with her companions apparently quite in her usual health, suddenly put her hand to her head exclaiming "Oh, my head!" gave a cry, fell down, and was in a minute or so very sick. The parents were at first inclined to ascribe the attack to a Christmas surfeit but on raising her into a chair they discovered that "she had lost the use of her limbs." I saw her about an hour afterwards. She had been very sick and was still inclined to retch. She was reclining in an armchair in a semi-comatose condition, her pupils were dilated and fixed, her temperature was 97·8° F., and her pulse was uncountable. The mouth was drawn over to the right side of the face, the head was inclined to the right shoulder, and her left leg was quite paralysed, but the left arm, so far as I could make out in a somewhat hasty examination in unfavourable circumstances—an ill-lighted crowded hut—was not so much implicated. About 4 A.M. on Jan. 1st she tried to "turn over" in bed, made an abortive attempt at vomiting, and quietly died. The father is a strongly built "ganger"; the mother is a weakly anæmic rheumatic woman, has a large family, and one sister suffers from constantly recurring tonsillitis.

A necropsy made on Jan. 4th disclosed a hæmorrhage which, starting from some vessel in the corpus striatum or optic thalamus, had literally ploughed its way into the right lateral ventricle, the resulting clot completely filling the cavity.

Though the diagnosis was confirmed I am quite at a loss to account for the condition revealed. My colleague, who kindly assisted me at the necropsy, and myself do not profess to be expert pathologists but we could find absolutely nothing to account for the attack, all the other organs being, macroscopically at any rate, quite healthy.

London

A CASE OF EXTRACTION OF A COIN FROM THE ŒSOPHAGUS.

BY JAMES LINTON BOGLE, M.D. EDIN.

IN connexion with the case of extraction of coins from the gullet published in THE LANCET of Dec. 10th, 1904, p. 1641, the following one may be of interest as occurring about the same time in my own household.

The patient was a boy, aged five years, who on Dec. 9th whilst playing with a 10-centesimi piece (being 1·2 inches in diameter and much the same size as a penny) put it into his mouth and accidentally swallowed it. He complained of pain at the back of his throat and in the stomach and was repeatedly sick, vomiting the food last taken. There was no interference with breathing and he readily swallowed liquids. Nothing could be seen or felt on careful examination of the throat and gullet save some slight reddening of the fauces. He was held up by the feet and well shaken without result. The vomiting continued for 24 hours, when the gastric pain became less. He had regular action of the bowels and took liquids and semi solid food without difficulty. On the 14th—i.e., five days afterwards—the coin had not been voided per rectum, there was still some irritation in the throat, the boy's voice was somewhat weak, and he still could not take solid food. He was therefore on that day taken to San Remo, where, through the kindness of one of my medical *confrères*, an excellent skiagram was taken by the x rays, showing very clearly the coin impacted in the gullet just above the sternal notch, being two-thirds above and one-third below the sternum. Under chloroform attempts were then made to remove it, either by bringing it up or pushing it downwards but unsuccessfully, mainly owing to the want of suitable instruments. As the x ray apparatus still showed clearly the shadow of the coin in the same position I telegraphed to Dr. J. A. Macdougall of Cannes, who kindly came next day to our assistance. Chloroform having again been administered a long flexible coin catcher was passed and at the first attempt this brought up the coin to the rima glottidis. There it was nearly lost again, falling forwards, but it was successfully removed by forceps. The coin had already much changed in appearance, being dark green and somewhat roughened at the edges. The little patient was sick for 24 hours but was in his usual health in three or four days' time. The feature of the case was the smallness of the disturbance caused by the presen [illegible] boy easily swallowed [illegible] dings with fluids and [illegible] the first.

Bordighera, North Italy

OF

HOSPITAL PRACTICE, BRITISH AND FOREIGN.

> Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv., Proœmium.

SOUTH WIMBLEDON AND MERTON COTTAGE HOSPITAL.

A CASE OF RUPTURE OF THE PANCREAS; OPERATION; RECOVERY.

(Under the care of Dr. A. H. GERRARD, Dr. MARTIN RANDALL, and Dr. PATTISON ARMSTRONG.)

FOR the notes of the case we are indebted to Dr. Randall.

The patient was a man, aged 42 years, a carman. On May 13th, 1904, at 9 A.M., he was walking backwards, leading a pair of horses in a loaded van. He went too far and got jammed between his own van and a stationary laden wagon. The pole of his van hit him in the epigastrium. He had violent pain, became faint and collapsed, and vomited. There was no history of blood in the vomit. He was taken to hospital and seen at 10 A.M. by Dr Gerrard who found him collapsed, ashen in colour, with a weak, small pulse of 90, a temperature of 95° F., and in great pain. He at once ordered stimulants, warmth, and a hypodermic injection of half a grain of morphine. It was ascertained that the patient had had breakfast at 8 A.M. and had passed urine at 8.30. Dr. Randall saw the patient with Dr. Gerrard at 11.30. He was still collapsed and in pain. Midway between the ensiform process and the umbilicus was a bruise nearly two inches in diameter and very tender to the touch. The skin was not broken. The abdomen moved but was very tender, especially above the navel. Liver dulness was normal. There was marked dulness in the right flank. From the gravity of the collapse, the site of injury, and the dulness it was concluded that the patient had some serious visceral lesion with internal hæmorrhage, and it was decided to operate if his condition seemed to warrant it in two or three hours.

Operation was performed at 3 P.M. by Dr. Randall with the help of Dr. Gerrard. Dr. T. Brice Poole gave the ether. A catheter was passed and drew off normal urine. A median incision was made above the navel. There was no gas in the peritoneum but much effused clotted and fluid blood. No lesion of the stomach, the liver, or the bowel could be found. A large tear directed vertically was then seen running from the stomach to the liver in the gastro-hepatic omentum and there was a tear in the peritoneum over the pancreas. Under this was a tear two inches long in the body of the pancreas, running from the right and below, upwards and to the left, leaving a loose tongue-like process of the gland, the base of which was half the width of the organ. On passing the finger through the tear it came directly on to the aorta. Oozing was free but no large bleeding vessel could be found. The rent in the pancreas was sewn up by four silk stitches passed by means of a curved needle in a holder. The smaller peritoneal sac having been cleansed the greater part of the tear in the gastro-hepatic omentum was sewn up with a continuous catgut suture, leaving a space above for drainage. The abdomen having been thoroughly flushed with hot saline solution an iodoform gauze packing was inserted down to the pancreas and the rest of the abdominal wound was closed. The operation was fairly well borne.

For the first three days the patient was constantly sick and in much pain. Morphine was used. Champagne stopped the vomiting on the evening of the third day. After this he was able to take small quantities of peptonised milk and panopeptone by the mouth. On this day he began to get delusions, thinking the medical attendants were going to poison or to injure him. He jumped out of bed, got the matron on the floor, and did the same the next night to a male attendant. At this time he seemed likely to die. The pulse rose to 150 and he became so collapsed that on May 20th he had $\frac{1}{30}$th of a grain of strychnine injected four times in nine hours, besides hot brandy and saline rectal injections. Bromides, sulphonal, and hyoscine had no effect in quieting him. Meanwhile the wound was healing and discharging abundantly a viscid, slightly turbid fluid which caused excoriation of the margins of the wound, rendering soothing ointments necessary. The patient was now extremely emaciated and had much bronchitis, with severe cough and much muco-purulent expectoration. The stitches were all removed on the 23rd, the lower part of the incision being healed. On the 26th the patient was sent to Kingston Infirmary as he was so noisy as to make the rest of the small building at disposal intolerable for other patients. His highest temperature was 100·2° on the 18th and the 24th. His pulse varied from 100 to 150. During his stay at the South Wimbledon Hospital no sugar was found in his urine and no special features were noticed about the motions.

Notes on the patient's history at Kingston, by Dr. ARMSTRONG.—On admission there was an incision about two inches long in the epigastrium, to the edges of which a piece of omentum was adherent, leaving two small openings near the upper angle of the wound. From these openings there was a profuse discharge of a whitish viscid fluid. The condition of the skin of the abdomen and the lower part of the thorax resembled that produced by an extensive burn of the first and third degrees. The patient was nervous, depressed, and suspicious, was very emaciated, and had a troublesome cough. Mucous râles could be heard over both lungs but were most pronounced at the left apex. His temperature was 100° F. The abdomen was dressed with boric ointment. Chloralamide (30 grains) was given and the patient slept for several hours.

With regard to the subsequent history, the wound gradually contracted, so that at the end of June there was only a sinus admitting a probe. Under the application of silver nitrate this soon closed. Two sutures presented in the wound on June 3rd and were removed. The bronchial trouble was gone by about June 6th. Examination of the sputum for tubercle bacilli gave a negative result but pneumococci were present. The fluid from the wound was at first viscid, mucoid, and alkaline in reaction and sufficient in quantity to soak the dressings in a few hours. Its irritant character was shown by its effect on the skin. It oozed continuously from the wound whilst the patient lay still but spurted out when he coughed. Later it got more watery. In one and a half hours a fluid ounce of it was collected. It had a slight digestive action on albumin. Its action on carbohydrates was not tried owing to difficulty in collecting fluid without causing discomfort to the patient. The quantity diminished as the sinus contracted and the flow had ceased a few days before the sinus was quite closed. There was very obstinate constipation until the patient was able to take ordinary diet. There was nothing peculiar in the motions. On June 8th the urine contained a small quantity of sugar. No sugar was present a week later. There was complete absence of chlorides. As to his mental condition, depression and anxiety were marked during the first three weeks. Narcotics were used for the first five nights to induce sleep. With regard to feeding, during the first fortnight peptonised fluids only were given and were well retained. Then, as the patient's condition had improved and he craved for solid food, a small quantity of pounded fish was given and was retained for about five hours. Violent vomiting accompanied by epigastric pain then set in and continued during the night, necessitating hypodermic injection of morphine. Peptonised diet was resumed for a week, then ordinary milk, peptonised farinaceous foods, &c., were given in succession, and on July 4th the patient was on a full diet. The changes of diet were accompanied by discomfort at first but no further vomiting occurred. The patient gained in weight and strength rapidly and left the infirmary on July 28th, the wound having been quite healed for nearly a fortnight.

Remarks by Dr. RANDALL.—The patient has now (Jan. 15th, 1905) been at work since the beginning of October as a carman, having to move and to lift heavy weights. He has some trouble with digestion. The scar bulges a good deal. The case appears worthy of recording because we have found no record of an analogous case successfully treated by operation. Dr. W. Hale White[1] refers to a similar case where no operation was performed. The patient died after a week with extensive fat necrosis. Another fatal case is referred to by Dr. R. Salusbury Trevor,[2] in which the patient died with fat necrosis and other lesions following injury to the pancreas by a kick from a horse. In the same article a successful case of operation for stab wound of the pancreas is mentioned. Injuries in this region are usually complicated, but the above two cases show that a severe uncomplicated trauma of the gland is not unlikely to be fatal. Hence there is some reason to think that the line of treatment adopted in this case was correct. For some days recovery was not expected. The vomiting and difficulty with the bowels were in all likelihood connected with some bruising of the sympathetic nerve plexuses behind the pancreas and it was not until several weeks after the accident that he was able to take anything except peptonised foods. The delusions were not, in our opinion, connected directly with the fact that the pancreas was injured but were the result of the severe shock on one with a history of mental trouble in the family. The violent outbreaks resulting would certainly have destroyed his life, apart from the prompt treatment of the ensuing collapse by strychnine and other stimulants. It seems difficult to imagine that recovery could have occurred in this case apart from operation when we consider the nature of the lesion and the amount of blood effused. If decomposition had not occurred fat necrosis would have been practically sure to follow and there was nothing to limit the action of the fluid to even the lesser peritoneal sac. From the physiological point of view there is not much to be said. Dr. Armstrong found sugar in the urine once, but it was tested on various occasions besides by all of us with a negative result. The motions showed no special features. That the discharge from the wound was largely pancreatic juice is evident from the condition of the skin and the tests used by Dr. Armstrong.

KIDDERMINSTER INFIRMARY AND CHILDREN'S HOSPITAL.

A CASE OF ANTHRAX (MALIGNANT PUSTULE) TREATED WITH PROFESSOR SCLAVO'S SERUM.

(Under the care of Mr. J. LIONEL STRETTON.)

A MARRIED woman, aged 35 years, was sent to the Kidderminster Infirmary and Children's Hospital by Mr. H. L. Miles on Dec. 23rd, 1904. On admission there was a well-marked malignant pustule situated on the chin just below the right angle of the mouth. Serum from the vesicles showed anthrax like bacilli. The history was that she had a small inflamed pimple in the same situation and she distinctly remembered rubbing the head off it on the 18th, it commenced to swell on the 20th and was well developed by the 22nd. Her husband was a wool sorter and had been working on Persian wool. He had a moustache and it was his custom each time he came home to kiss his wife. This made the source of infection tolerably clear. The pustule was freely excised and the wound was left to granulate. 80 cubic centimetres of Professor Sclavo's serum, divided into four portions, were injected into the subcutaneous tissue covering the abdomen at four different points. The after progress was satisfactory. Locally there was more suppuration than is usual. There was no considerable rise of temperature, the highest record being 99 2° F on the second and third days. On the fifth day she was able to be up and was discharged on the eighth day with a healthy granulating wound.

---

[1] Encyclopædia Medica, vol. ix., p. 89.

[2] Practitioner, April, 1904.

The excised pustule was forwarded to Dr C Duncan, analyst to the Worcester county council, and he reported as follows "The centre of the pustule was removed and teased up in distilled water. A few anthrax like bacilli were detected when the material was stained by the methods of Loffler and Gram. Three agar cultures of the material at blood heat developed a few typical anthrax colonies and many other colonies of cocci and bacilli. The material therefore contained living anthrax bacilli."

Remarks by Mr STRETTON —Although the successful issue cannot entirely be attributed to the use of the serum this case deserves to be put on record as one of the earliest treated with it in this country. From the history of the case it is probable that more than three days elapsed before the pustule was excised and from a considerable experience I have learnt that the chances of recovery are very slight if excision is delayed beyond 48 hours. Even within that time death has occurred in many cases so treated. I am not prepared at present to sanction the use of the serum without excision of the pustule as practised by Professor Sclavo. His results are so striking that it is probable future experience will prove this to be justifiable.

For the supply of serum I am indebted to Dr T M Legge, His Majesty's Medical Inspector of Factories, who has spared no pains in bringing this method of treatment before us.

Medical Societies.

CLINICAL SOCIETY OF LONDON

Exhibition of Cases

A MEETING of this society was held on Jan 27th, Dr FREDERICK TAYLOR, the President being in the chair.

Mr J P LOCKHART MUMMERY showed an Instrument for Examining the Rectum and the Sigmoid Flexure. The instrument was a slightly modified Strauss's sigmoidoscope by which a diagnosis might be made, thus avoiding exploratory laparotomy.

Mr J HUTCHINSON jun showed a case of Extensive Syphilitic Necrosis of the Skull causing an Intracranial Abscess but without any Cerebral Symptoms. The man contracted syphilis at the age of 18 years and was treated for a short while. Four years later he had rupia with severe pain in the joints, iritis, and posterior synechia in the left eye. Treatment was resumed. He remained free from symptoms for ten years until September 1904 when a lump formed on the vertex followed by sloughing of a circular patch of scalp then by necrosis of the skull beneath until the cerebral pulsations appeared but the man was meanwhile able to work, not suffering from headache, giddiness, or other cerebral symptoms until his admission to hospital. There the dead bone was removed by trephining and a large subcranial collection of pus was found between the skull and the dura mater.

Mr C H FAGGE showed a case of Uretero lithotomy for Calculus in a young girl. A girl, aged seven years had in 1901 pain in the right loin with hæmaturia. In 1903 the same symptoms returned and she was operated upon for an umbilical hernia. In September, 1904, she had a return of the pain, with a *tender spot two inches to the right of the* umbilicus and under an anæsthetic a small hard mass could be felt. A calculus was found in the ureter about one inch below the kidney which appeared to be normal. The calculus was removed and the ureter and abdominal wall were sutured. Healing followed and the urine became normal a week after the operation.—Mr DOUGLAS DREW suggested that it was important in such cases to examine the kidney, since a second stone might be present, and also to exclude the possibility of a suppurative pyelitis being present.

Dr F PARKES WEBER showed a case of Localised Flushing and Sweating on Eating, which, together with "Striæ Patellares," followed appendicitis ten years ago. The symptoms had persisted since *the former exhibition of the* patient in October, 1897. When he began to chew solids a patch of redness immediately appeared on the *left* cheek and the skin sweated. When this was at its maximum a smaller and less marked patch might appear in front of the *right* ear. Vinegar and water in the mouth also mastication movements of the jaws called forth the appearance to a *less marked degree. Swallowing did not produce the* phenomenon. After ceasing to chew, the sweating and then the redness slowly disappeared. The striæ patellares were well marked, like the lineæ albicantes gravidarum, and were attributable to the flexed position of the knees when suffering from appendicitis.

Mr CHARLES R KEYSER showed 1 A case of Goitre in a *boy, aged five years. A lump appeared in the neck in* September 1904 with anorexia, occasional vomiting and malaise. The swelling appeared to be a parenchymatous goitre and increased to the size of a hen's egg. The boy had always lived in London and no other member of the family had been similarly affected. The tumour had rapidly diminished under treatment by iodine and iodide internally and mercury iodide externally. 2 A case of Recklinghausen's Disease. A man, aged 38 years, had had all his life a number of small rounded subcutaneous tumours which were steadily increasing in number. He said that one brother was similarly affected and that his mother died from the disease. The tumours were all soft and absolutely painless, there were two *areas of pigmentation but there were no* signs of malignancy or of nervous disease. The patient was very deaf following scarlet fever in childhood, and suffered from chronic bronchitis and emphysema.

Dr H BATTY SHAW showed 1 A case of Acromegaly in a man, aged 36 years. Enlargement of the fingers and hands had been noticed for four or five years and numbness and tingling for three years. A radiogram of the hand showed the changes in the phalanges. Eight or nine years ago the patient wore No 6 boots, now No 8, the great toe was markedly enlarged and the skin was thicker. The skull had enlarged, the eyelids were thickened, the nose was broadened, the wrinkles on the face were deepened, and the voice was hoarse but the eyes and vision were normal and there was no kyphosis. The patient was sometimes troubled by headache and by drowsiness. 2 A case of Acromegaly occurring in a woman *the subject of Chronic Disease of the* Chest. The patient was now in the Brompton Hospital for Consumption under Dr S H Habershon with disease of the left chest. The hands and fingers had enlarged and also the feet, the malar eminences were prominent, the lower lip was protruded as were the eyelids giving a heavy dull expression. The tongue was enlarged. The patient suffered from headache, insomnia and morning vomiting but there were no eye symptoms. Photographs and radiographs further illustrated the case and distinguished it from pulmonary hypertrophic osteo arthropathy. 3 A case of Bilateral Wasting of the Subcutaneous *Tissues of the Face in a boy, aged 10* years. This commenced after the age of two and a half years. Three years ago he attended the Victoria Hospital for Children and the wasting *became more marked after measles* two years ago. The wasting appeared to affect the subcutaneous tissues but not the skin, muscles or bone. The condition was bilateral. There was no muscular paralysis or wasting in any other part. The patient had had no illness except some slight rheumatic symptoms and choreic movements.

Mr W G SPENCER showed the case of a boy three years after Removal *of a Large Cystic Adenoma of the Left Kidney*. In the summer of 1901 when the boy was aged 12 years the mother first noticed the swelling but she said that he had always had a "big stomach". In January, 1902 the boy was first taken to Dr Redmond Roche who diagnosed the case

Abdominal nephrectomy was performed by a T-shaped incision; some vascular adhesions of the diaphragm caused a temporary disturbance of respiration. The half of the specimen in the Westminster Hospital Museum was shown and Mr. S. G. Shattock's description of the other half in the Museum of the Royal College of Surgeons of England was appended.—Mr. HUTCHINSON, jun., suggested that as only part of the kidney was affected a partial nephrectomy was all that was necessary and he had in one case removed half the kidney for such a condition.

Mr. SPENCER also showed a child after recovery from Infantile Paralysis of the Deltoid. He said that when the subject of nerve-grafting for such cases was before the society in October last the girl was in Dr. F. de Havilland Hall's ward and could not then raise the arm from the side at all. The child had been kept under Dr. Hall's observation and had had the arm rubbed and electricity used. She could now raise it easily above the head and seemed to be recovering well.

Dr. F. E. BATTEN showed a child with Graves's Disease and Myxœdema at the age of ten years. She was a fat child, with a pale puffy face and hands, squeaky voice, and placid slow manner, and had considerable thyroid enlargement and a pulse-rate between 118 and 140. She had a waddling gait. Other signs of nervous or visceral disease were absent. 13 weeks ago the child fell downstairs; 11 weeks ago headache came on with such severity that the child had to be kept in bed; and six weeks ago the enlargement of the neck and puffiness of the face were first noted.

Sir DYCE DUCKWORTH showed a case of Xanthoma Diabeticorum. The patient, a man, aged 23 years, had diabetes in September, 1904. A sister died from the disease at the age of 31 years. He was first of all treated privately, then at St. Thomas's Hospital, and was admitted to St. Bartholomew's Hospital in December. On Dec. 24th a large number of small papules appeared over both elbows. The papules were hard, shotty, and a small amount of yellowish material could be pressed out. On the 31st the papules had increased in size and fresh ones appeared symmetrically over the back, the buttocks, the knees, and scantily on the face. On Jan. 25th the papules were increasing in size and number. The amount of urine averaged 100 ounces per diem and was of specific gravity 1034. Perchloride of iron reaction was present. The sugar on admission was 25 grains per ounce and on Jan. 25th it was 12 grains per ounce. The body-weight on admission was 8 stones 6 pounds; on Jan. 25th it was 7 stones 8 pounds.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases.—Milk-supply of Edinburgh.—Friedreich's Ataxia.

A MEETING of this society was held on Jan. 18th, Professor JOHN CHIENE, the President, being in the chair.

Dr. W. ALLAN JAMIESON exhibited a case of Psoriasis which illustrated the effect of oxidised pyrogallic acid in treatment. The patient was a man, aged 31 years, who exhibited the gyrate form of the disease. Treatment was commenced on Nov. 7th, 1904. An ointment of chrysarobin, salicylic acid, and ichthyol was applied and caused the characteristic erythema and considerable improvement. The outer margins of the eruption remained, however, red and raised. In place of the chrysarobin, oxidised pyrogallic acid was added to the ointment which was rubbed in twice daily after a bath containing fluid superfatted potash soap. The skin became very dark brown and assumed a silky smoothness in contrast to the desquamation which followed the use of the chrysarobin. Owing to the improvement produced the treatment was discontinued on Jan. 7th, 1905. Dr. Jamieson also showed a case of Lupus treated by the x rays after a prolonged period of rest. The patient was a girl, aged 15 years. The disease commenced in 1899 on the right cheek in several patches. Various remedies were employed but no improvement resulted. She had been treated partly with the Marshall and Wood's lamp and partly, and more particularly, with the x rays between September, 1902, and February, 1904. A few nodules which remained were treated with fused chromic acid. Nothing had been done since September, 1904, and the lupus seemed to be cured.

Dr. W. G. AITCHISON ROBERTSON read a paper on the Milk-supply of Edinburgh, with Suggestions for its more stringent Control. After mentioning the closeness of the relation between the milk-supply and the hygiene of infancy he referred to the great frequency of infantile diarrhœa caused by the presence of "dairy bacteria" in milk. He said that the amount of lactic acid present in milk might be taken as a very fair standard of the degree of putrefaction present and it was his custom to determine the freshness or staleness of milk by the percentage of lactic acid present. Applying this test to milk as sold in some of the shops in the poorer districts of Edinburgh, Dr. Robertson found that during the summer in 54·8 per cent. of these dairies the acidity of reputedly fresh milk was above 0·181 per cent. If lactic acid were given even in minute amounts to infants it produced gastric and intestinal catarrh, and if tubercle bacilli of bovine origin were introduced into an intestine with a mucous membrane already weakened by the ingestion of such acid milk all the conditions were present for the easy passage of such tuberculous organisms into, and through, the mucosa. He believed it was in this way that abdominal tuberculosis was developed. He then proceeded to discuss the reasons for tuberculosis being so common amongst dairy cows. At present there were in Edinburgh 115 cowsheds licensed to contain 3417 cows. In many cases byres containing from 20 to 40 cows were situated in densely populated localities, often behind lofty tenements and approached by narrow lanes or alleys. From the time when the cows were bought until they were again sold they were never allowed out from such byres; this might mean a period of close confinement lasting from nine to 15 months and occasionally for much longer periods. The cows were also greatly overcrowded. The cubic space recommended by the Local Government Board for each animal was 800 cubic feet, but in many of the older cowsheds in Edinburgh only 600 cubic feet were allowed to each cow and yet on measurement of the available air space to each animal he had found in many instances only from 370 to 450 cubic feet. He was of opinion that at least 1000 cubic feet should be allowed to each cow and that this should be distributed over a far wider floor-space than was customary. After all, however, the amount of cubic space was not to be compared in importance to the amount of fresh air which ought to be supplied to each animal. As a rule the dairy-keeper objected to too free a ventilation as it lowered the temperature of the byre and so the yield of milk became lessened. In consequence of the insufficient amount of cubic space and the totally inadequate supply of fresh air the air in cowsheds was apt to be much vitiated. He was thoroughly convinced that the extreme prevalence of tuberculosis in dairy cattle was due entirely to these factors—namely, overcrowding, insufficient ventilation, and want of sunlight and exercise. Tuberculosis in cows had made an immense advance during the past few decades and this corresponded to the period during which prolonged detention of animals in cowsheds had been the custom. He affirmed that every one of the city cowsheds ought to be abolished and that every dairy farm should be in the country in order that the cows might live healthy lives and so yield healthy milk. In order that this might be attained the animals must be allowed to graze in meadows during the entire day and should, if necessary, only be confined in freely ventilated and roomy sheds during the cold nights of winter. The yield of milk would be smaller but the quality would be superior to that of stall-fed cattle. Maternal nursing ought to be encouraged and he alluded to the inducements in this respect held out to mothers in many towns of France and recently introduced into Huddersfield by the mayor. If this were unattainable then all milk destined for the use of infants and children ought to be pasteurised, and thus "prepared milk depôts" were a necessity in towns and such must be controlled by the local authorities and supervised by medical men.—Dr. G. H. MELVILLE DUNLOP said that Edinburgh was behind continental and other cities as regarded the proper control of the milk-supply. He proposed that a committee of medical men should be appointed to inquire into the milk-supply of the city.—Dr. JAMES CARMICHAEL said that Dr. Robertson had wisely laid emphasis on the necessity of medical men advising mothers to nurse their children but he had not alluded to the fact, too evident in the present day, that unfortunately in town communities the proportion of mothers able to do so was diminishing. Sterilisation of milk, he thought, was not now necessary; pasteurisation had largely taken its place and was [illegible] purc [illegible] of a [illegible] of h [illegible] authorities at present had in regard to the control of cowsheds and dairies. Special by-laws would be necessary to enable the changes indicated to be made.—The following gentlemen were nominated to serve on the committee: Dr. Dunlop, Dr. Carmichael, Dr. J. S. Fowler, Dr. William Robertson, Dr. H. Harvey Littlejohn, and Professor Chiene, with Dr. Aitchison Robertson as convener.

Dr. **HARRY RAINY** read a paper on the Nature of Friedreich's Ataxia. In it he gave an account of the lesions found in a case which he had investigated and the pathological conclusions which these observations appeared to warrant were that (1) the nature of the degeneration was uniform; (2) the distribution of the degeneration (as observed in the posterior columns of the cord) indicated that the lesion followed the course of the individual nerve roots; (3) the primary lesion seemed to be a premature dis- [illegible] elements, either from deficient [illegible] -elopmental defect perhaps associ- [illegible] production; and (4) the degenerated nerve elements were replaced by interstitial tissue which by degrees cicatrised and so formed at first whorls, then later a felted mass of fibres. This process might gradually encroach on healthy areas. There was probably a marked increase in the number of mesoglial cells.—Dr. **ALEXANDER BRUCE** and Dr. **D. CHALMERS WATSON** took part in the discussion which followed.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

Cholecystotomy.—Prostatectomy.—Exhibition of Patient.

A MEETING of this section was held on Jan. 13th, Mr. G. **JAMESON JOHNSTON** being in the chair.

Mr. **R. C. B. MAUNSELL** read a paper entitled "Cholecystotomy for Acute Cholecystitis following Typhoid Fever." The cholecystitis manifested itself on the twenty-seventh day after the patient's admission to Mercer's Hospital, Dublin. The muco-pus removed from the gall-bladder contained a pure culture of Eberth's bacillus. Mr. Maunsell briefly described the affections of the gall-bladder which might complicate enteric fever and he strongly advocated operative treatment. In looking up the literature of the subj [illegible] com- plications arising 14½ yea [illegible] some of these cases pure cult [illegible] were obtained.—Mr. JAMESON [illegible] es of typhoid fever in which [illegible] ng for surgical intervention. [illegible] f the laryngeal cartilages and in the other there was a chronic abscess of bone and in both of them typhoid bacilli were found in the pus.—Sir **CHARLES BALL** said that he had [illegible] ny [illegible] ch, [illegible] ed [illegible] hat in his opinion the question of interest in Mr. Maunsell's case was whether the acute cholecystitis was a complication of the acute fever or a sequela. These complications were to be expected [illegible] the patient [illegible] think typhoid [illegible] in the prese [illegible] numbers in the gall-bladder without any results, locally or otherwise, in the neighbourhood.

Mr. **C. A. K. BALL** introduced a discussion on Con- [illegible] patient without inflicting permanent injury to important to explain Dr. Young's operation of conservative perineal prostatectomy, showing that the lateral and median portions of the prostate could be removed without injuring the mucous membrane of the bladder or the urethra and ejaculatory ducts, a matter of some importance now that prostatectomy was being done in younger men. The mortality after the perineal operation was less than half the mortality after the suprapubic operation.—Mr. **JAMESON JOHNSTON** stated that he had always performed the suprapubic operation and still thought it the right one. He did not think that there were such things as lobes in the enlarged prostate; the prostate was simply adenomatous and there was no definite lobar arrangement. The ingenious idea of Lane's operation was to be admired—namely, the preservation of the ejaculatory ducts.—Mr. **EDWARD H. TAYLOR** stated that he had been present at Mr. Ball's prostatectomy operations and was impressed by the ease with which the prostate could be exposed by means of a curved incision in front of the anus and the facility with which the capsule could be peeled off the lateral lobes and the large veins of the vesico-prostatic plexus avoided. Against the operation was the fact that it entailed an extensive dissection and division of the compressor urethræ muscle. There was considerable risk therefore of injuring the sphincteric apparatus of the bladder and of subsequent incontinence of urine. There was much less risk of incontinence with the suprapubic operation.—Mr. **JOHN LENTAIGNE**, Mr. **STONEY**, and Sir **THOMAS MYLES** also took part in the discussion.

Mr. **MAUNSELL** showed a patient upon whom he had operated for Acute Cholecystitis and subsequently for Gangrenous Appendicitis.

EPIDEMIOLOGICAL SOCIETY.—A meeting of this society was held on Jan. 20th, Dr. B. A. Whitelegge, the President, being in the chair.—Dr. G. B. Longstaff read a paper on the Etiology of Rheumatic Fever, beginning with [illegible] before the society in [illegible] tly published in his [illegible] paper he had called [illegible] of a relation between erysipelas, puerperal fever, scarlet fever, and rheumatism, the graphic curves of the first two being practically identical. He had found no connexion whatever between cold and the prevalence of rheumatism but a sort of inverse relation with the rainfall nearly as close as that between diarrhœa and hot weather. Dr. A. L. Galabin in 1902 having pursued the same line of investigation into another 20 years confirmed the identity of the curves of erysipelas and puerperal fever even in years when these were most [illegible] from those [illegible] all septic [illegible] e puerperal [illegible] hich scarlet fever was most frequently attended by septic complications streptococci were most widely diffused, the streptococcus pyogenes being the cause of septic and purulent complications in all specific and non-specific diseases. The new classification of rheumatoid diseases by the Registrar-General removing ulcerative endocarditis from valvular diseases had lessened the similarity of the curves of rheumatic fever and erysipelas and given the former a very characteristic one of its own. In opposition to the teaching of Dr. Charles Murchison, Dr. J. S. Bristowe, and Dr. F. T. Roberts the present school represented by Professor William Osler and Dr. I. Burney Yeo had transferred acute rheumatism to the class of acute infective, though non-contagious, diseases of microbial origin and placed ulcerative endocarditis among the septic. Dr. A. Newsholme's exhaustive examination of the prevalence and fatality of rheumatic fever in many countries and its association with dry seasons had contributed greatly to this change of opinion. The error of ascribing the disease to "chills" had, like all errors in etiology, an influence for evil on therapeutics. Under the new classification rheumatic fever and rheumatic affections of the heart and pericardium, excluding chronic valvular diseases and ulcerative endocarditis, were classed as rheumatic fever and rheumatism of the heart and pericardium. Rheumatoid arthritis was rightly transferred to other constitutional diseases as unwisely was rheumatic gout, which was gout pure and simple, the few remaining causes of death in rheumatic persons being provisionally entered as residual rheumatism. Many deaths, however, from chronic valvular disease of the heart were due to previous attacks of rheumatic fever. After noting the numerical changes consequent on the re-arrangements of the classification Dr. Longstaff proceeded to discuss the geographical distribution of the deaths from rheumatic fever and rheumatism of the heart and pericardium. The death-rate in the period 1891 to 1900 was everywhere except in Wales notably less than it had been in 1881–90, but in each the London and north-western districts stood highest and the east and northern midland lowest, Wales, however, mounting from next the lowest to a place between Yorkshire and London. In all this there was not the smallest indication of a connexion with temperature or humidity. Curves representing the death-rates at each age in the former period, in which acute and subacute rheumatisms were relegated to the miscellaneous group of what he would call residual rheumatism, showed the former more fatal in early life and the latter after middle age. But while the transfer of acute and subacute rheumatism and its inclusion under rheumatic fever and rheumatism of the heart had had no effect on the curve, which still had its maximum between the ages of from 5 to 15 years, it had converted the curve of the residual group from one in which the deaths from the acute forms neutralised the effect of those from the chronic into one in which they saw a regular ascent from childhood to old age, culminating between the sixty-fifth and seventy-fifth years, a character further emphasised by the removal of rheumatoid arthritis and of rheumatic gout. The causes of rheumatic fever seemed to be gathering strength during the latter months of summer, the maximum intensity of the disease being in November.—Sir W. S. Church expressed his distrust of statistics, especially international, in which the fallacy of differing nomenclatures was added to that of doubtful diagnosis. For instance, the *rheumatisme grave* of the French in which empyema was an occasional complication could not be the same as the disease called acute rheumatism in England. What, he asked, were the causes of death in the group of so-called residual rheumatism since the chronic disease was not itself fatal? The prevalence and mortality of rheumatic fever in London and Yorkshire were explained by the fact of its being an urban disease as was its recent increase in South Wales. All army statistics opposed the climatic theory of its causation. Ulcerative endocarditis was set up by a totally different microbe.—Dr. Newsholme said that the mortality of a disease like rheumatic fever with a fatality of less than 2 per cent. gave a very imperfect index of its prevalence and that, as with diphtheria, the great importance of local conditions was concealed in statistics drawn from the whole country or from large districts which effaced the peaks and depressions of the curves indicating local epidemics or their absence. However their curves might resemble one another the smallest prevalence of erysipelas corresponded with the greatest of rheumatic fever. The idea of a relation between rheumatism and the specific infective fevers was not new, having been indicated by Prout, Trousseau, Farr, and others according to their lights. He maintained the influence of subsoil, even in London, and remarked that rheumatic fever was epidemic after very dry years.

Harveian Society.—A clinical meeting of this society was held at the Stafford Rooms, Tichborne-street, Edgware-road, London, W., on Jan. 26th.—Dr. J. J. Perkins showed a man suffering from Addison's Disease. There were pigmented spots on the skin and in the mouth. There had been faintness on micturition but no attacks of vomiting. Dr. Perkins also showed a young man suffering from Bronchiectasis who had been much improved by tracheal injection of creasote in oil. He had gained in weight.—Dr. H. Batty Shaw showed a patient with Recklinghausen's Disease associated with Dilated and Dropped Stomach. The patient was admitted to University College Hospital in February, 1904, under the care of Dr. Sidney H. C. Martin. Mr. R. J. Godlee also saw the patient and discovered on the body and head from twenty to thirty small subcutaneous masses which caused pain on pressure; two were excised and found to be fibromata lying in close relation to nerves. A few days ago the patient was again examined; the pigmentation and flat warts had increased. In addition the stomach was found to be lying in the suprapubic region; it was greatly distended and when in peristalsis caused severe colicky pains. No tumour could be felt.—Mr. E. Laming Evans showed a case of Severe Multiple Deformity in a girl, aged 14 years, following infantile paralysis at 14 months which had received no treatment. Besides a severe lateral deviation with rotation of the spine, a bulging of the anterior abdominal muscles, and a double calcaneo-cavus, all of paralytic origin, there was a contracture at the hip-joints of 135 degrees. As a compensatory curve, the degree of lordosis was extreme.—Dr. Maurice F. Squire showed a man, aged 31 years, with a history of Right Otorrhœa all his life, Gonorrhœa, and Sores, but no Secondary Symptoms. Two weeks before Christmas, 1904, he commenced vomiting, which had continued intermittently ever since with headache. He complained of frontal headache of variable intensity. Vomiting was occasional and with a little preceding nausea. Mentally the patient was rather dull. There were no alteration of sensation or movement, no incoördination, and no localised tenderness. There was doubtful flattening of the left face. Movements of the eye were normal but there was marked right optic neuritis. With regard to the ears, there was an old dry perforation in the left ear and a large polypus was removed from the right ear where there was a slight discharge. A few days ago he had some retraction of the head. The patient was rather improved since the removal of the polypus but the symptoms and physical signs suggested the question of cerebral or cerebellar abscess. As there was no localising symptom he proposed to wait and to watch events.—Mr. E. Percy Paton showed a man, aged 55 years, who first began to notice a swelling on the right side of his neck nine months ago which had increased in size. He thought there could be no doubt that the mass was malignant and inoperable and also that the growth was primary in the neck, either being sarcomatous and commencing in the glands or carotid body or possibly epitheliomatous in connexion wtih the remains of one of the branchial clefts. His impression was that it was an endothelioma beginning in the lymphatic glands or the carotid body.—Dr. Leonard G. Guthrie showed a man, aged 52 years, who had for seven or eight years complained of increasing difficulty in walking. There was no history of syphilis. The condition was probably one of steady progressive degeneration in the neighbourhood of the corpora quadrigemina and perhaps of the left cerebellum or its peduncles. It would probably result in paralytic dementia or tabetic general paralysis.—Dr. Alexander Morison showed a case of Bilharzia Hæmatobia in a man, aged about 30 years, who had been a cavalry soldier in the South African war. Hæmaturia was first noticed after bathing in the Blood river.

Society for the Study of Disease in Children.—A clinical meeting of this society was held on Jan. 20th at Chandos-street, W., Dr. Percy G. Lewis being in the chair.—Mr. F. Jaffrey showed two cases of Volkmann's Contracture which had occurred in the right forearms of two girls, aged two and seven years respectively, as a result of fractures.—Dr. W. H. Kelson showed a boy, 12 years of age, whom he had treated by the galvano-cautery for Lupus of the Epiglottis and Left Vocal Cord, the voice returning. The upper part of the epiglottis was wanting and the stump had been covered with red papules. The ventricular bands, the left vocal cord, and the anterior commissure were similarly affected. There were no history of syphilis, no evidence of lung disease, and no tubercle bacilli in the sputa.—Dr. L. G. Guthrie showed a girl, aged 12 years, whom he brought before the society in December, 1903, as a case of Aortic Stenosis. He was still of the opinion that the physical signs indicated aortic disease and thought that there might be some congenital malformation in the neighbourhood of the aortic valves. The girl was highly rheumatic. As on the former occasion, various opinions were expressed on the physical signs and the conclusions to be drawn from them.—Dr. A. Morison showed a boy, ten years of age, with marked Double Aortic Disease and Mitral Regurgitation. There was an indefinite history of rheumatism.—Dr. G. Carpenter showed a child with Congenital Pulmonary Stenosis and probably a Patent Septum Ventriculorum.—Mr. Donald J. Armour brought forward a boy, aged four years, with a Peno-scrotal Form of Hyposadias with a view to elicit the opinion of members of the society as to the best kind of operative treatment and the best age at which to carry it out.—Dr. G. E. C. Pritchard showed a girl, six years of age, to illustrate Hæmophilia, hereditary in the male line for two generations and evidenced in the third in a severe form in a female. The child had suffered from severe attacks of epistaxis since babyhood. Her father and grandfather were affected but no other members of the family.—Mr. G. Pernet showed a case of Generalised Lichen Planus of three month's duration in a boy aged six years. The boy had a "tower skull," ptosis, with absence of the upward movements of the eyes, and a highly arched palate. He also showed a child, aged four months, recently vaccinated, with a Circinate Gyrate Erythema Multiforme.—Dr. J. G. Emanuel (Birmingham) showed a most remarkable specimen of Congenital Multiple Occlusions of the Small Intestines from a seven months' infant who died nine days after birth. The child had vomited since birth but no stool had been passed. As the result of an enema a large motion of meconium was passed. There was complete atresia of the bowel at the duodeno-jejunal juncture, the duodenum being much hypertrophied and dilated, being larger even than the stomach. In two other places the jejunum was completely absent for about half an inch. In five other places, in the jejunum and upper part of the ileum, the gut was completely occluded by annular constrictions. There were no signs of intra-uterine peritonitis.—Mr. A. T. Marshall showed a specimen of a Collar Stud impacted in the Œsophagus and Perforating the Trachea. It was removed post mortem from a female infant, aged seven months. It had produced consolidation of the right lung, ulceration into the trachea an inch above the bifurcation, and pus in the trachea and the œsophagus.

HUNTERIAN SOCIETY.—A pathological meeting of this society was held on Jan. 25th, Mr. John Poland being in the chair.—Mr. Poland showed a Fallopian Tube removed from a Femoral Hernia; the ovary was not seen.—Mr. W. H. Kelson showed a very extensive Carcinoma of the Larynx obtained from a patient shown at the society a year ago. Tracheotomy had been performed and later, when the growth spread back to the œsophagus, nasal feeding was resorted to. The patient suffered very little pain and died from asthenia.—Mr. Hugh M. Rigby showed a specimen of a Tuberculous Stricture about the middle of the jejunum. Just above the stricture there was an ulcer which had perforated and produced general peritonitis. The perforation was sutured and invaginated. A lateral anastomosis had been performed four inches above the stricture. The patient had experienced no symptoms from the stricture until perforation occurred. He died the day after the operation from the peritonitis due to the perforation.—Mr Harry Overy (introduced by Dr. W. Langdon Brown) exhibited a very well-marked example of Congenital Syphilitic Liver cleft into many Lobules by Deep Fissures. Several large gummata were also present in the liver. The microscopical sections showed perilobular and intercellular cirrhosis. The spleen was much enlarged and cirrhosed. The kidneys were lardaceous. Mr. Overy also showed Two Kidneys taken from the same patient. The one was small and studded with many cysts of the size of hazel nuts. The other was large and fibrous. Sections of the two kidneys were identical in showing chronic interstitial nephritis. The patient was 53 years of age.—Mr. J. H. Targett took the view that this was a case of congenital cystic kidney.—Mr. H. L. Barnard thought that these kidneys showed an intermediate stage in the formation of acquired general cystic disease of the kidneys. He did not think the adult form was in any way congenital or connected with the Wolffian body but was simply an exaggerated form of the small cysts so generally seen in granular kidneys.—Dr. H. Russell Andrews exhibited a specimen of Fibroids of a Double Uterus which he had removed by abdominal hysterectomy.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Jan. 20th, Dr. David Newman, the President, being in the chair.—Dr. Alfred A. Young showed two patients who had been operated upon for Ruptured Gastric Ulcer and he read the notes of two other cases. The two patients were operated on within six hours of the rupture. In both cases the stomach was empty at the time of the perforation. The ulcers were situated about the middle of the lesser curvature, one on the posterior and the other on the anterior surface. In neither case was there much fluid in the peritoneal cavity at the time of the operation and this was washed out and the abdomen was closed without drainage. In neither case was the ulcer excised. The patients made a good recovery. A third case was operated upon 24 hours after perforation when the whole of the abdomen was distended and full of brownish septic fluid. There was a history of an attack six days previously which seemed to point to a perforation which had been recovered from. At the operation a large perforation was present on the anterior wall with adhesions around it and a smaller one a little distance off. The peritoneum was much inflamed. The perforations were closed and the abdomen was washed out as well as possible. The abdominal wound was stitched without leaving any opening for drainage. The patient went on very [illegible] was f[illegible] diapl[illegible] patient died on the fifth day after the second operation. A fourth case was that of a [illegible] who was suddenly seized [illegible] with great collapse an[illegible] there was no general [illegible] feeding the patient made a good recovery. This was taken to be a case of perforation limited in its effects by adhesions.—Dr. MacLennan showed two patients upon whom he had performed Riedel's Operation for Chronic Osteo-myelitis of the Tibia. A number of x ray plates were shown to illustrate the regeneration of bone. The operation consisted in chiselling, gouging, or scraping the anterior part of the tibia away till only a strip connected the cancellous ends. If the disease started originally in the epiphysis it was cleared out, the epiphyseal cartilage being carefully protected. After some months the adherent scar was excised and a linear cicatrix moveable upon the tibia resulted. Dr. MacLennan was strongly of the opinion that more bone lesions which resisted less drastic treatment ought to be treated as if the medulla were infected and the shaft mostly removed. The method was applicable to other bones. The results v[illegible] ought to be treated by the [illegible] it to separate.—Dr. Willi[illegible] Etiology and Pathology of Scarlet Fever.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY.—A meeting of this society was held on Jan. 18th, Dr. W. V. Snow being in the chair.—Dr. C. W. Buckley read a paper entitled "Climatology from a Medical Standpoint." Dr. Buckley said that the study of climatology from a medical standpoint must be subjective rather than objective. Meteorological observations were only of value as interpreting our sensations of weather which were composed of a very complex association of climatic factors and had not been sufficiently studied from that aspect. Even the subjective sense of atmospheric temperature was a complex of temperature, humidity and wind, while such climatic characters as bracingness were made up of these factors, together with pressure and, to a less extent, sunshine. He discussed in detail the effect of each factor on the system and briefly indicated the combinations which they entered into in producing their conjoint effects. Reference was made to a series of observations taken in Shanghai, under the direction of Mr. W. F. Tyler, and by means of charts the important influence of the absolute humidity on the bracingness of a climate was indicated and also the fact that the readings of the wet bulb thermometer were a more trustworthy guide to the subjective temperature than of the dry bulb. In conclusion [illegible] desirability of the society undertaking the [illegible] limates from the subjective [illegible] o discover definite relations [illegible] meteorological readings.—Dr. F. Bagshawe said that in some municipalities provided with a staff of official observers meteorological records were looked for from that source only and thus individual observers were few. In the study of local climates the influence of some winds formed a leading factor in determining the climate of a place. Warmth and absence of fog were promoted by hills screening from northern currents while free exposure to southern breezes freshened the air. Relaxing places were often surrounded by hills.—Dr. W. Ewart, Dr. F. Rufenacht Walters, Dr. F Parkes Weber, Dr. W. J. Tyson and Dr. S. D. Clippingdale also discussed the paper.—Dr. Buckley, in reply, quite agreed that meteorological statistics of rainfall and rainy days were no indication of the number of days fine enough for an invalid to go out and said that although the subjective method of recording variations of weather was open to fallacy, [illegible]acies arose from the present method of [illegible] from records of one or two meteorological factors. He w[illegible] absolute humidity was of more [illegible] a medical standpoint had received so much support.

ROYAL MEDICAL SOCIETY, EDINBURGH.—A meeting of this society was held on Jan. 20th.—Dr. J. M. Beattie read a paper on the Pathology of Rheumatism. In the course of his remarks he discussed the bacterial theory of the disease, giving a detailed account of its history and the evidence upon which it rested. In three fatal cases of rheumatism he had been successful in obtaining from the knee a micrococcus similar to the organism found by Poynton and Paine. In one of these cases he had obtained this micrococcus in pure culture from the spleen and in impure culture from the urine. The organism was a small diplococcus sometimes arranged in short chains. On inoculating rabbits with this micrococcus he was able to recover it from the urine, knee, heart blood, and brain. After considering the theories which suggested that the condition was really due to an attenuated pyæmia or streptococcal septicæmia he concluded by stating that the micrococcus was plainly the specific organism and the cause of rheumatic fever.—Mr. T. Graham Brown read a paper on Brown-Séquard Epilepsy.—Dr. Wilson-Smith read notes of two cases of Acute Nephritis in which the capsule of the kidney was stripped.——At a meeting of the society held on Jan. 27th Mr. N. C. Forsyth read a dissertation by Dr. C. R. T. Mitchell on Head Injuries. He first briefly discussed the anatomy of the scalp and went into the subject of scalp wounds, dividing them into those which penetrated and those which did not penetrate the aponeurosis of the occipito-frontalis muscle. He continued by giving the various lines of treatment for each class. The next subject to be taken up was that of facial wounds and Dr. Mitchell treated this part of his subject more especially from the standpoint of facial disfigurement. He then went on to define the term concussion and discussed the diagnosis, treatment, and complications of the condition, giving a full description of the operations practised when the middle meningeal artery was severed and favouring Chiene's met[illegible]site for trephining. He then took up [illegible] of the head, balancing the various theories of causation and adopting the view that the site of the fracture was determined by the bursting of the skull at its weakest point. Dr. Mitchell also discussed the various methods of treatment and concluded by touching lightly on fractures of the bones of the face and on intracranial suppuration.—Dr. V. T. Carruthers showed two cases of Tumours.—Dr. Chambers showed a case of Addison's Disease.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held at the Royal Infirmary, Bradford, on Jan. 17th, Mr. C. F. M. Althorp, the President, being in the chair.—Mr. Vaughan Bateson showed some photographs of a case of Sarcoma of the Scapula and Magnified Finger-prints as used for personal identification under the new system of classification adopted by the Government. He then read a paper on a case of Granuloma Fungoides. The clinical history was given and the remarkable deformity produced was well illustrated by photographs, the great changes of the facial condition at different stages of the disease being well shown. The details of the history and the report of the pathologist were of an interesting nature and especially the connexion, causative or otherwise, of a flagellated bacillus found in the tumour masses. Its rarity and the obscure pathology made the subject one for a brisk discussion which followed the paper, Mr. J. Basil Hall, the President, and Dr. F. W. Eurich taking part therein.—Dr. A. Bronner read a paper on the Local Use of Orthoform in the Treatment of Painful Ulcers, with special reference to tuberculous laryngitis. Used with boric acid powder, 1 in 10, in these cases, it was surprising how complete and immediate the relief was. Dr. Bronner also said that its use was equally beneficial in cases of burns, fissure of the anus, and gastric ulcer.—The President, Dr. Campbell, Dr. W. E. Heilborn, and Mr. Hall took part in the discussion.—Dr. Bronner replied.

NEWPORT MEDICAL SOCIETY.—A meeting of this society was held on Jan. 25th, Dr. T. Morrell Thomas, the President, being in the chair.—Several interesting cases were exhibited and discussed.—Dr. T. G. Lewis read notes on a Case of Intestinal Hæmorrhage.—Mr. J. McGinn read notes on a Case of General Tuberculosis with Unsatisfactory Result from Surgical Interference and Decisive Improvement under Open-air Treatment.—Mr. C. Brooke Gratte read notes on a Case of Post-partum Hæmorrhage treated with Adrenalin Chloride.

Reviews and Notices of Books.

A Treatise on Applied Anatomy. By EDWARD H. TAYLOR, M.D. Dub., F.R.C.S. Irel., Surgeon to Sir Patrick Dun's Hospital; University Examiner in Anatomy and late Lecturer in Applied Anatomy, Trinity College, Dublin; Member of the Council and late Examiner in Surgery, Royal College of Surgeons, Ireland. Illustrated with 178 figures and plates from original drawings, many printed in colours. London: Charles Griffin and Co., Limited. 1904. Pp. 738. Price 30*s.* net.

WE have perused this work with considerable satisfaction. The author states that his object has been to provide an account of the regional anatomy of the human body in its more important applications to medicine and surgery. He, like most others of practical experience, is an advocate of the teaching of anatomy to students of medicine from the applied standpoint. This method was some years ago instituted in the medical school of Trinity College, Dublin, and also by one, if not more, of the larger London hospitals. The arrangement adopted by Dr. Taylor appears to us an excellent one. A concise but not sketchy account of the anatomy of each region is given in small type and the practical bearing of anatomical facts on the diseases and the injuries of the region in question is then discussed. Embryology and its influence on congenital malformations come in for a due share of the author's attention. The main scope of the book, as would be expected from the author's proclivities, is surgical; medicine receives a certain amount of attention but nothing like that devoted to surgery. In fact, the author admits that the title of "Surgery from an Anatomical Standpoint" would well describe his book. The treatise differs from the majority of the English text-books which deal with the same subject in the amount of anatomy which it contains. This feature will render the book particularly useful to those who are preparing for the final surgical examinations as well as to those whose anatomy is getting rusty from lapse of time. The anatomical descriptions, as we have already indicated, are concise, but, what is more important, they are essentially in accordance with modern teaching and methods of description. The surgical bearings are in every instance fully considered and afford a useful and interesting commentary on the anatomical facts.

A regional arrangement has been adopted under the following main headings: Head and Neck, Upper Extremity, Thorax, Abdomen and Pelvis, and Lower Extremity. In the section on the Brain the author explains and illustrates his own method of determining the topography of the principal fissures and convolutions on the outer surface of the cerebral hemisphere. A review is not the place in which to describe the method but when compared with those at present in vogue it most resembles that of Anderson and Makins and, like this method, is said by its author to be elastic and applicable to skulls of varying size and contour, contrasting in this respect with the methods of Reid and of Hare. We miss any representations of the segmental nerve areas of the body. This is surely an oversight. The illustrations are deserving of great praise. Most of them are original, being drawn from specimens in the medical school of Trinity College, Dublin, by Mr. James T. Murray of Edinburgh. They have been chosen with care and discrimination and really illustrate the points *under* discussion. For commendation we especially single out those devoted to visceral topography and the anatomy of hernia. We predict that this treatise will take a prominent place amongst the many books dealing with the same subject. It has obviously cost its author much time and labour and we unreservedly congratulate him on the great measure of success which he has achieved.

A Manual of Surgical Diagnosis. By JAMES BERRY, B.S. Lond., F.R.C.S. Eng., Surgeon to, and Lecturer on Surgery at, the Royal Free Hospital; formerly Surgical Registrar and Demonstrator of Anatomy, of Operative Surgery, and of Practical Surgery at St. Bartholomew's Hospital. London: J. and A. Churchill. 1904. Pp. 363. Price 6*s.* net.

DIAGNOSIS is probably the most difficult part of surgery to the student. He can learn and repeat glibly the causes, signs, symptoms, and treatment of a disease or injury but he is often completely at a loss when confronted with a case. This book will help the student in the difficult task of distinguishing between various conditions which have signs in common. Of course, diagnosis is not to be learnt from books but in the out-patient room and in the ward, and there the student must go to learn it, but a book like this may be of much service to the diligent and careful student who is anxious to advance in his work; it will show him how to apply in practice the knowledge he has already acquired in theory. The author has, we think, acted wisely in limiting the scope of the work to the more common conditions, for it is these which will especially be encountered both by the student and the practitioner. It is not possible to include in a volume intended for the student the whole of surgical diagnosis. The book is well and carefully written and is a reflex of the author's surgical experience. To one point we should like to call attention. On p. 305 the term melæna is apparently used as synonymous with "blood in the motions"; this is a pity, for both etymologically and by usage it should be restricted to the dark tarry stools which owe their colour to altered blood.

Light Energy: Its Physics, Physiological Action, and Therapeutic Applications. By MARGARET A. CLEAVES, M.D., Fellow of the New York Academy of Medicine; Fellow of the American Electro-Therapeutic Association; Professor of Light Energy in the New York School of Physical Therapeutics, &c. London: Rebman, Limited. 1904. Royal 8vo, pp. 827. Price 21*s.* net.

THIS book is sure to be welcomed by those members of the profession who are directly or indirectly interested in the therapeutic application of the various forms of light energy. The subject is treated from the basis of the modern theory that light is energy in the form of waves of a certain length and direction, with a slight reservation in favour of the emission theory in view of the peculiar behaviour of some of the recently discovered radio-active substances—notably radium. About 130 pages are devoted to a description of the various kinds of rays, their origin and physical properties. The part dealing with the electric arc is very complete and clear and embraces all that is requisite to insure an intelligent application of the arc lamp in the treatment of disease. Then follows a series of chapters on the action of light on the various forms of life from the most elementary to the highly complex human subject. In this section the action of light of different kinds from both natural and artificial sources is treated in a very thorough manner. It is quite evident that the author has devoted herself to a large amount of painstaking experiment, the valuable results of which are recorded in the present volume. In her experience the mercury vapour lamp has not justified the expectations regarding it as a therapeutic agent.

The second half of the book is taken up with the therapeutic applications of light in its varied forms. Sun, arc, and incandescent baths are fully dealt with and also their use in those diseases in which the author has found them respectively of service. The indications are in every instance based on spectroscopic analysis and full details of the proper technique are given for every variety of application. Several forms of bath cabinet are described as well as arc and other lamps for local treatment with concentrated light. While the author is emphatic on the necessity of employing lamps of large amperage—quantity being as essential as quality—yet she speaks highly of certain small lamps the efficiency of which was so low as to necessitate their replacement by lamps of greater power in the light department of the London Hospital. The reason is seen later to be related to the comparative cost of the lamps, the smaller being sold and maintained at a fraction of the cost of the Finsen lamp and their efficiency is at least in proportion to this cost. According to this author the great advantage of a lamp of high amperage, like the Finsen, is that we get not only the short and high frequencies of intense chemical activity but also the frequencies of long wave-lengths having great amplitude and penetrability—a combination which is essential to insure the best success. In the smaller lamps these long wave-lengths of great amplitude are not present in such abundance because of the lesser amperage and smaller carbons.

The results which the author has obtained in many diseases not generally subjected to light treatment will come as a surprise to those who have not kept closely in touch with modern light therapeutics. The applications of light of various colours, as also those of the invisible spectrum rays, are fully discussed. A short chapter is given to the consideration of "n" rays and one to the alpha, beta, and gamma rays of radio-active substances, their physical properties, actions, and therapeutic uses. An interesting chapter is that on fluorescence, fluorescent stimulation, and sensitisation of tissues, and the book closes with a chapter on the occasionally injurious effect of sunlight and the pathological effects of electric lighting. The x rays have not been included in the volume since that subject is so extensive and has been so ably dealt with by others.

Leadless Decorative Tiles, Faience, and Mosaic. By WILLIAM JAMES FURNIVAL. Stone, Staffordshire: William J. Furnival. Pp. 852. 1904.

AS medical journalists our interest in the ceramic art is centred in the question of the effects of the industrial operations concerned upon the health of the workers. Foremost amongst the proposals to improve the sanitary conditions of those engaged in the pottery trade has been that of dispensing with as far as may be practicable, raw lead or even "fritted" compounds used in glazing and substituting glazes entirely free from lead. No one has contributed more usefully and more energetically to the advancement of this subject than has the author of the interesting and handsome volume before us. Mr. Furnival has attacked the question in a very practical way: he has given to the world a number of formulæ for the preparation of leadless glazes and these formulæ, we are assured, give satisfactory results. At any rate, in a report published in 1899, Professor T. Oliver and Professor T. E. Thorpe, as specially appointed commissioners for the Government, wrote: "We have no doubt whatever that leadless glazes of sufficient brilliancy, covering power, and durability and adapted to all kinds of table, domestic, and sanitary ware are now within the reach of the manufacturer, and we have reason to believe that this fact is now more generally admitted by the trade itself than it was six months ago. ...... Leadless glazes are equally applicable to white, cream, buff, and printed tiles. We have seen excellent examples of tiles so glazed." In 1898 Mr. Furnival published a book entitled "Researches on Leadless Glazes" which was reviewed in THE LANCET of Nov. 19th, 1898.

This book, as was then pointed out, contained the important results of a great number of laborious experiments directed to the practicability of producing leadless glazes and employing them in pottery. The work before us, whilst dealing with further researches of this kind, covers much wider ground, including such interesting subjects as a historical review of decorative tile work, the rise of the modern industry, the sources and preparation of clays, materials, and colourants, ceramic pyrometry, mosaic pavements and mural decoration, and so forth. When we add that there is scattered throughout the pages a series of admirable plates illustrating both ancient and modern tile work it will readily be conceded that the work is not only technically but æsthetically interesting also. Some of the photo-blocks illustrating Babylonian clay tablets, Assyrian enamelled bricks, Syrian and Turkish tiles, Indian enamelled tile work, and mosaic turrets are cases in point. Many of the blocks are three-coloured and others are monochrome and lithograph. The historical treatment of the subject has induced Mr. Furnival to seek the assistance of certain well-known authorities. Thus the work includes the following interesting and well-written contributions:—Notes on the Decorative and Architectural Use of Glazed Tiles and Faience in China, by Dr. Stephen W. Bushell, for over 30 years resident physician to H.M. Embassy at Peking, author of "Oriental Ceramics"; A List of the Principal Existing Monuments in India upon which Tile Work Decoration appears, by Mr. C. Stanley Clarke, of the Indian Section, Victoria and Albert Museum; Notes on the Tile Decoration found on Buildings in Punjab and Bengal, by Mr. J. H. Marshall, Director-General of Archæology, India; and Designing for Ornamental Tile Work and Faience, by Mr. Ambrose Wood, Hanley, Staffordshire. Altogether it is a very interesting and attractive volume which is sure to be consulted by all those who are engaged in the technical matters of the ceramic art, who are concerned with it in its relations to the use of deleterious materials, and who make the application of art to decorative work a serious study. We congratulate Mr. Furnival on the completion of what must have been a big task. Finally it may be pointed out that according to the returns of cases of lead-poisoning in the potteries for 1904 there is a decided increase. Whereas there were 87 cases in 1902, 97 cases in 1903, the number has reached 106 for 1904. These facts furnish an excellent *raison d'être* for the publication of this volume.

LIBRARY TABLE.

Examination Questions. Edinburgh: E. and S. Livingstone. Pp. 283. Price 2*s.*—This is a collection of questions set for some years past at the various medical examinations held by the University of Edinburgh, the Royal Colleges of Physicians and Surgeons of the same place, and the examiners for the qualification of the Triple Board. They are brought down to July, 1904. The collection should certainly be useful to those preparing for examinations as showing them the class of questions which they may expect to meet.

A Star Calendar for 1905. London: Hirschfeld Bros. 1904.—This calendar consists of four sheets containing the calendar for three months on a sheet, together with a star chart for the same three months showing the appearance of the sky between 7 P.M. and 10.30 P.M. To those who live in the country this chart will be found of great interest but the dweller in London or other large town will find it of but little use, for even on a clear night, which is rare, he can only see the stars in the zenith or near it on account of the smoky air. Moreover, his horizon is contracted by houses and the light from street lamps seriously interferes with his view of the stars.

Vegetarian and Simple Diet. By Colonel A. R. KENNEY-HERBERT. London: Swan Sonnenschein and Co. 1904. Pp. 450. Price 3*s.* 6*d.* net.—While fully convinced of the general advantages of a mixed diet, we think it probable that many people, especially those who live a sedentary life, eat too much meat. This being so we are glad to welcome the appearance of a book which will teach householders that appetising dishes can be made from vegetables with the aid of eggs and milk products. Of course there is one great difficulty in the case of town dwellers (and they are just the class of persons whom a superfluity of meat harms)—namely, that it is almost impossible to get fresh vegetables. The difference between a cabbage or a cauliflower cooked when just cut and those which have been packed for days in a market cart or have been imported from Brittany or even the Channel Islands is enormous. But even London vegetables are better than none and Colonel Kenney-Herbert's book gives admirable recipes for cooking and serving the same. We are particularly glad to see his anathema of the ordinary English "melted butter," that abominable compound of "corn-flour' and water with possibly a little butter or milk. His directions for cooking rice are altogether admirable but we are rather surprised that he has omitted any reference to garlic as a vegetable, although he mentions it as a flavouring. Garlic which has been blanched in three or four waters and finally gently stewed in a little stock makes a delicious dish and the garlic flavour is by this treatment so attenuated that nine people out of ten who partake of it do not know what they are eating.

Vegetables and their Cultivation. By T. W. SANDERS, F.L.S. London: W. H. and L. Collingridge. Pp. 463. Price 5*s.* net.—This little book gives a description of vegetables used for cookery, salads, and flavouring, together with directions for their cultivation and an account of garden friends and foes. Of course its main value will be to dwellers in the country but we wish that Mr. Sanders had laid more stress than he has upon the custom which every gardener follows of refusing to cut vegetables until they are fully grown. Globe artichokes in particular can be nearly all eaten if they are cut young enough; no gardener, moreover, will ever pull either beans or peas until they are far too old to be at their best for eating. Horticultural shows have a great deal to answer for and are mainly responsible for "mammoth peas" and "giant potatoes." The small early grey-green pea is of far finer flavour than the great hulking marrowfat which is the joy of the London greengrocer but of course it takes a great many more small peas to make up a pint or a pound than it does big ones, hence from the commercial point of view growing small peas is unprofitable.

The Crusade against Phthisis. By A. B. DE GUERVILLE. London: Hugh Rees, Limited. 1904. Pp. 34. Price 6*d.* net.—This is a brightly written description of the treatment carried on at Dr. Otto Walther's sanatorium at Nordrach-Colonie. It is from the pen of a layman and the pamphlet does not contain any point which is not well known and understood by the members of our profession. It is a tribute by a sufferer who has recovered to the physician who has done so much for him.

I. I-Em-Hotep and Ancient Egyptian Medicine. II. Prevention of Valvular Disease. The Harveian Oration, 1904. By RICHARD CATON, M.D. Edin., F.R.C.P. Lond., Consulting Physician, Royal Infirmary, Liverpool. London: C. J. Clay and Sons. 1904. Pp. 34.—The first part of this oration is archæological, dealing with Egyptian medicine, the medicine god, and the earliest inquiries known to have been made concerning the circulation and circulatory diseases. The information gathered concerning the line of study to which Harvey devoted his attention is of a most interesting nature and is presented by the orator in a charming manner. The text is illustrated by various views of temples either built by, or in the days of, I-Em-Hotep, who was distinguished as a "physician, a minister of the king, a priest, a writer, an architect, an alchemist, and as an astronomer—great in all, but greatest in medicine." In the second part of his oration Dr. Caton presses on the attention of the profession the necessity for the special treatment of recent valvulitis. The treatment advocated is to secure the most absolute quiet and rest for many weeks; to administer sodium or potassium iodide, partly to help in the absorption of morbid exudations but chiefly to lower vascular tension; and lastly, to endeavour to influence the cardiac vaso-motor and trophic nerves reflexly by gentle and almost painless stimulation of those cutaneous nerves which we know to be in close relation with the heart—viz., the first four dorsal nerves.

Materia Medica of Vegetable and Animal Origin. By JOHN HUMPHREY. With an Introduction by E. M. HOLMES, F.L.S. (Kimpton's Pocket Text-book Series.) London: John Kimpton. 1905. Pp. 495. Price 5*s.* net.—This is a well-arranged little book which will be valuable both to students of pharmacology and to pharmacists. It contains all that it is necessary to know about crude drugs of vegetable and animal origin. The uses of the drugs are dealt with concisely, the chemistry is brought up to date, and the book is well indexed. All the unofficial drugs in common use, as well as those which are official, are dealt with. It is a handy pocket volume but it will naturally be of more service to the druggist than to members of the medical profession. The drugs are dealt with in alphabetical order. The author is a practical pharmacist.

Familiar London. By ROSE BARTON. London: A. and C. Black. 1904. Pp. 208. Price 20*s.* net.—London for many of us has the extraordinary fascination that alcoholic drinks have for the dipsomaniac. We would fain get away from it but we cannot. And in this book we find Miss Rose Barton confessing with her pen, "I never leave London without a pang," and when we look at the reproductions of the charming drawings from her brush with which the book is illustrated we do not wonder at her confession. All those who live in London will be delighted with the book, for besides the illustrations, many of which will be familiar to those of our readers who visit the exhibitions of the Royal Water Colour Society, Miss Barton has written a gossiping account of various London localities, scenes, and celebrities which will give many a Londoner information which will be new to him. How many, for instance, of the thousands who go up and down the Strand every day know the meaning of the heads on the keystones of the arches supporting the basement of Somerset House?

Hazell's Annual for 1905. Edited by W. PALMER. London: Hazell, Watson, and Viney. Price 3*s.* 6*d.* net. Pp. 756.—The 1905 issue of this valuable Annual is in no way inferior to any of the foregoing. It is impossible really to review a work of this kind but we may say that the Annual before us gives information upon all kinds of matters with which the ordinary educated British subject should be familiar. One pleasing feature of the work is the absolutely impartial manner in which such burning questions as education and religious matters are treated. It is extremely difficult for anyone who cares at all seriously about such subjects to write impartially upon them. It is also equally difficult for anybody who does not care to write intelligently and with knowledge but "Hazell's Annual" seems to have overcome these difficulties. The Annual is a worthy pendant and complement to "Whitaker."

Diaries.—We have received from Messrs. Bemrose and Sons, Limited, 4, Snow-hill, London, E.C., and Derby, twelve little books, each measuring about three and a half inches by two and a quarter inches, with pleasing dark-green paper covers, one for each month of the year. They are known as Bemrose's Monthly Diary and are of a most convenient size to go into the waistcoat pocket. Each day of the month has a page allotted to it and at the back of the diary is a page for memoranda and a folio for a cash account. On the second page of the cover is a calendar for the year and on the third page is a list of some inland postal regulations. There are only two little things to which we take exception —the odd appearance of "Whitsun Day" for Whit-Sunday or Whitsunday and the popular error of "Parcels" Post for Parcel Post.

JOURNALS AND MAGAZINES.

Edinburgh Medical Journal.—With the year 1905 this journal celebrates its centenary, as it was founded in 1805 under the title of the *Edinburgh Medical and Surgical Journal*, appearing quarterly under the editorship of the younger Andrew Duncan. In 1855 it was amalgamated with a younger contemporary, the *Monthly Journal of Medical Science*, and has appeared ever since under the title which it then assumed as a monthly magazine. It has been presided over by a series of distinguished medical luminaries and owing to the high position which it has always occupied it has been the medium for the publication of papers from many notable representatives of medicine. Hence its pages afford material for an almost continuous history of the advances which have been made since its foundation. The January number is devoted to a retrospect of its past achievements in the form of a series of articles dealing with notable contributions to medicine, surgery, obstetrics, and the allied sciences which are to be found in its back numbers. The result is a most interesting and instructive chapter of medical history. Some excellent portraits of past editors are included.

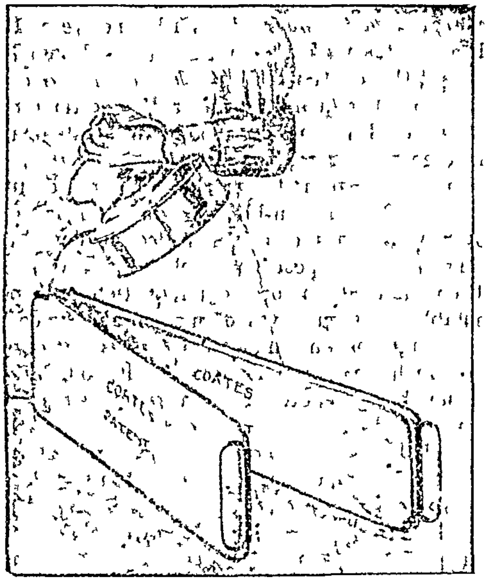
Dublin Journal of Medical Science.—The January number of this periodical opens with an article by Sir William Thomson on Operative Methods, New and Old, in Tuberculosis of the Knee-joint, which is practically devoted to a vindication of excision of the articulation. The author records a series of 78 cases in which this operation was performed, with two deaths, and quotes very satisfactory results obtained by Sir Thornley Stoker and Sir Thomas Myles. Sir Arthur V. Macan deals at considerable length with Accidental Hæmorrhage and sums up his experience in a number of propositions, from among which we will only quote the opinion that rupture of the membranes is not good treatment for ordinary cases of this nature unless it causes rapid expulsion of the child. Mr. E. F. Stephenson reports a case of glanders in a human subject, the site of infection being apparently the mucosa of the mouth; the facts recorded tend to show that the bacillus mallei can exist for so long as two years in a virulent condition in stable manure.

West London Medical Journal.—To the current number of this magazine Dr. A. E. Russell contributes an interesting paper on the Diagnosis of Acute Abdominal Disease. He quotes statistics showing that of all such cases no less than 37 per cent. are due to affections of the appendix vermiformis, whereas only 6 per cent. are due to pelvic conditions. Dr. C. H. Fennell writes on Mental Deficiency in Children in regard to Prognosis, and Mr. Stephen Paget contributes an interesting lecture upon Head Injuries, in which he alludes to the benefit derived by a certain number of patients suffering from such conditions from venesection—a practice which in these days has fallen into perhaps undeserved disrepute—and discusses the indications for trephining. Among the Society Proceedings is recorded and illustrated a case of unilateral lesion of the tenth, eleventh, and twelfth cranial nerves with resulting paralysis of the sterno-mastoid and trapezius muscles, as well as of the soft palate, the vocal cord, and half of the tongue on the same side.

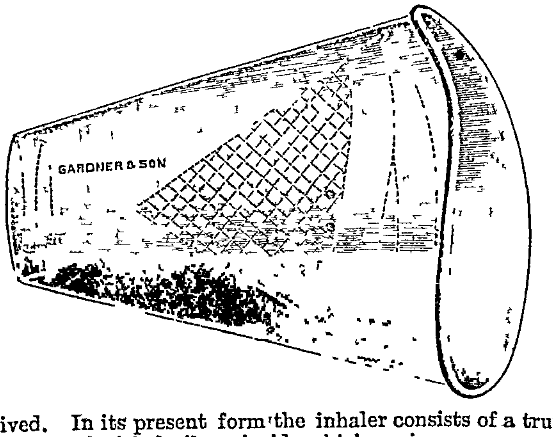
New Inventions.

A NEW BED AND FOOT WARMER.

THE accompanying illustration shows an ingeniously designed bed and foot warmer which will probably be found useful in hospital and nursing-home work. It is made in two portions hinged together at the ends by a removeable pin, so that when opened it is four feet long—i.e., large enough to warm the whole length of a bed or the whole width of a double bed. When closed it measures two feet long and forms an excellent foot warmer. Each half can be used separately for different beds if required. In the illustration the warmer is represented partly open and the method of filling it is shown. It is solidly and neatly made in block-tin and also in copper, the price being 7*s.* 6*d.* in the former material and £1 2*s.* 6*d.* in the latter. It holds six pints and weighs about eight pounds when filled. The patentee and maker is Mr. F. Coates, 14, Thavies Inn, Holborn-circus, London, E.C.



A STERILISABLE INHALER FOR ANÆSTHETIC MIXTURES.



THE accompanying figure represents an inhaler which has been made to my order by Messrs. Gardner and Son, Forrest-road, Edinburgh. I wish to draw attention to this apparatus because it is not an addition to the great number of inhalers already on the market but merely an improvement on one which was introduced several years ago by Mr. Clarence Blake of Boston and which deserved more favour than it received. In its present form the inhaler consists of a truncated cone of nickel silver, inside which a wire gauze cone is retained by a spring. The former has an opening at the top about one inch by two inches, the lower opening measuring five inches by three and a half inches. The whole inhaler, which weighs only six ounces, can be sterilised by boiling and in using it a piece of one and a half or two inch domette bandage about one and a half yards long is wrapped about the inner cone before each administration, rather more being needed if ether alone be employed. In certain cases a piece of sponge with large pores is placed in the upper aperture when a full vapour of ether is desired. The inhaler is intended chiefly for the administration of A.C.E. or C.E. mixture but ether alone can be conveniently administered by means of it as stated, or even ethyl chloride, but for this last a bag inhaler is preferable. From its simplicity, adaptability, and portability the apparatus may prove to be particularly useful to medical men whose work is in the country, who only occasionally are called upon to administer an anæsthetic, and who require an inhaler which will not spoil in keeping or readily get out of order.

T. D. LUKE, M.B., R.U.I., F.R.C.S. Edin.,
Lecturer in Anæsthetics at the University of Edinburgh.

Looking Back.

FROM

THE LANCET, *SATURDAY*, Feb. 3, 1827.

The following WORKS[1] *have been received.*

L'Agent immediat du Mouvement Vital, devoilé dans sa nature, et dans son mode d'action chez les vegétaux, et chez les animaux. Par M. H. DUTROCHET, Correspondant de l'Institut, dans l'Academie Royale des Sciences, &c.

The author of the above work endeavours to elucidate the vital movement in the animal and vegetable kingdoms, by an explanation of the course that the juice takes in plants, and the causes of its propagation. M. Dutrochet thinks that the progression of liquids in vegetables, and in living bodies generally, is the result of a particular form, capable of accumulating them in a much greater quantity than could be done by simple capillary action. He establishes his opinion upon a series of experiments, in which, having placed in water a sac formed of an organic membrane, filled with very thick animal paste, he saw, after half an hour's immersion, the solid paste in great part driven from the sac by the water, which traversing its parietes, introduced itself into the cavity of the sac. Different experiments led the author to recognise that every time an organic membrane is interposed between two liquids of an equal density, a movement of one of those liquids takes place across the membrane; the movement being in general effected from the liquid possessing the least towards that possessing the greatest density. The power by which the liquid is pushed into the interior cavities, M. Dutrochet calls *endosmose*, and the contrary action *exosmose*.

The experiments of the author also show that alkalies placed in the interior of a membranous sac, always produce endosmose; while the acid under the same circumstances, produce exosmose, whatever may be the density of the liquids. This last circumstance leads the author to believe that the cause of such a phenomenon is purely electrical, and that the membrane in which it operates, holds the place of a permeable Leyden jar. In modifying his experiments according to this idea, M. Dutrochet placed an organic membrane in the inferior part of the tube, between two heterogeneous liquids, the one within the tube, the other without; by these means he succeeded in making the lowermost liquid pass into the tube, and in elevating it so as to make it pour over the sides. This effect is always maintained, up to the putrefaction of the membrane; all animal membranes, all vegetable textures have afforded the same result. The author also remarked, that in making the two extremities of a galvanic pile communicate with each side of the membrane, the liquid is always carried from the positive pole, or the least dense, towards the negative pole, or the most dense. The elevation of the temperature sensibly favours the endosmose, on which account the author thinks that inflammation in animals may be considered as a perendosmose. Whether the theory be correct or not, it is not our intention at present to discuss; we have seldom perused a work possessing so much valuable physiological knowledge, and we strongly recommend it to the attention of our readers.

---

[1] The work reviewed above is the first of a list of seven received and summarised

THE LANCET.

LONDON: SATURDAY, FEBRUARY 4, 1905.

The Encouragement of Biological Research into the Nature of Disease.

THE importance of a sound biological training as a preliminary equipment for attacking some problems of disease is becoming more fully recognised. As proofs of this recognition we may cite the following instances. The knowledge of this necessity has determined some recent appointments in connexion with the London and Liverpool Schools of Tropical Medicine. There is talk of the University of London attempting to give concrete expression to the significant bearing of certain lines of zoological research on some of the pressing problems of disease. An influential body of men has founded a society for the encouragement of the study of economic zoology. The investigations of the Imperial Cancer Research Fund have been moulded on comparative biological lines, and we have reason to believe that a new director of the cancer investigations at Liverpool has not been appointed for the sole reason that it has not been possible to secure a candidate with the needful qualifications for biological and cytological work. The Carnegie trustees in Scotland have given grants in aid of biological inquiries into the nature of cancer and in a recent address Professor HEKTOEN has urged the importance of biology upon the medical profession in America. From all this it will be seen that the relation of biology to the elucidation of disease is very much in the air, and deservedly so.

The biological nature of some aspects of the cancer problem has been frequently urged in our columns, but with every desire to encourage the serious biological investigation of disease it is not always easy to discriminate between the essentially biological papers which possess the practical medical bearings claimed for them and those which do not. This is all the more difficult when the customary medical nomenclature is replaced by the technical terminology of the biologist and the familiar pathological problem is presented dressed up in biological phraseology. We publish to-day a paper on cancer by Dr. JOHN BEARD, lecturer on comparative embryology in the University of Edinburgh, which is the third of a series that has appeared in our columns. The writer states that it is based on work carried out with the support of the ample funds for research at the disposal of the Carnegie trustees and the Moray Research Fund of the University of Edinburgh. We have thought it well to find space for this paper, for it seems to us to be a serious matter that it has been produced with the countenance of the wealthiest endowment for research in this country. The present contribution is itself the best commentary and criticism upon the two previous articles and its character makes it incumbent upon us to state clearly the illogical reasoning upon which Dr. BEARD's conclusions are based, seeing that they have already received qualified acceptance from some pathologists who probably would not subscribe to a bald statement of the fundamental conceptions upon which a fantastic but seemingly logical superstructure has been raised.

This germ-cell hypothesis of cancer has been expounded in terms of the conception which its author entertains of the nature of vertebrate development. It must be clearly understood that the truth or the falsity of this hypothesis of cancer *is dependent on the truth or the falsity of the embryological* theories upon which it is based. These theories led Dr. BEARD to affirm in a former paper[1] that they necessitated the limitation of carcinoma to the mammalia in which division of the animal kingdom it was "a sequel to uterine gestation." This prophecy has not been fulfilled. The embryological views have not been modified but other investigators have shown that carcinoma is common to all vertebrates and the germ-cell hypothesis of cancer has quietly accommodated itself accordingly. Dr. BEARD never tires of reminding us that his embryological conclusions do not find general acceptance. After due inquiry into their nature we must confess that much of what is fact for Dr. BEARD remains very hypothetical to us. Our confidence in his conclusions is not restored by the assurance "that all the wonderful and infinite variety of animate nature" (including the neoplasms) "has its fount in *the unconscious memories of germ cells.*" Interpretation of all the facts of embryology in accordance with this view is without our province; but the "unconscious memory" of the germ cell—that it has had something to do with a chorion in past generations—leads us to recognise that for Dr. BEARD all malignant new growths are merely chorion (trophoblast, blastoderm, asexual generation of Dr BEARD), which masquerades as a squamous-celled epithelioma or in the guise of the columnar cells of a malignant adenoma, or, indeed, in the garb of any one of the many histological groups of the carcinomata and sarcomata. The chorion is alleged to have unlimited powers of growth and to take on the histological character of the tissue in which it is growing provided that it develops without an embryo. The cancerous chorion develops from a germ cell without an embryo by skipping the embryonic stage in the life-cycle which Dr. BEARD has laid down for the vertebrates. The cancerous chorion naturally arises anywhere in the body, for it is said that the germ cells do not all find their way into the sexual organs. They are scattered through the tissues, where they lie dormant or grow, and we are at once brought face to face with all the old difficulties associated with COHNHEIM'S "rests." The difficulties are but shifted back in the scale of development from the embryonic tissues to the germ cells. The "unconscious memory" of the germ cell is, however, elastic. It remembers that it has got to produce a chorion which has conveniently to mimic the tissues surrounding its nidus but the chorion breeds true to the character of the primary nidus in metastases. In assuming for the chorion unlimited powers of growth the germ cell—and Dr. BEARD with it—forgets that chorion does not possess such inherent powers of growth any more than does any other tissue of the embryo or the adult. On the contrary, the assumption of such unlimited powers of growth is contradicted by accumulated pathological and experimental experience. In this connexion it is only necessary to refer to the very recent work of Schmorl on the frequency with which chorionic villi become arrested in the vessels of the lungs during pregnancy without evincing any signs of growth. The "unconscious memory" of the germ cell is potent for evil. It conjures up "an ancestral acid peptic" digestion for the chorion and endows it with "an acid and eroding action," "for only by such could a cancer erode bone." We wonder if the aortic aneurysm which erodes its way through the sternum or the vertebral column owes this power to the same unconscious memory.

---

[1] THE LANCET, June 21st, 1902, p. 1758.

In short, Dr. Beard passes from one conjecture to another. He begins by views on embryology which on his own showing are not generally accepted by embryologists. He goes on to express opinions on the histology and the pathology of cancer which are not in accordance with known truths and launches into the realm of therapeutics with assertions about the action of ferments which would inevitably cause the rejection of a candidate in physiology. We are anxious to encourage the serious biological investigation of cancer and we trust that we are doing so by eliminating from the hypotheses worthy of future consideration one characterised by more wild speculations in more fields of knowledge than any other with which we are acquainted. In the present chaotic state of the cancer problem there is much preliminary clearing up to be done and we can only regret that our opinions on the nature of those biological investigations of cancer which are worthy of financial support differ so essentially from those entertained apparently by the Carnegie trustees and the Moray Research Fund of the University of Edinburgh. In estimating the value of contributions such as that which we publish to-day much larger issues are raised than the mere scientific value of the paper itself. By the indiscriminate distribution of funds for research purposes proper support may be diverted from more important research in the true sense of the word and the question of the competence and the responsibilities of those administering funds for research purposes may obtain a prominence unfavourable to the reputation of British scientific medicine.

◆

Myelopathic Albumosuria.

In The Lancet of Jan. 28th we published an article by Dr. C. W. Paget Moffatt on Myelopathic Albumosuria. This is a condition which has received little attention in medical text-books but communications on the subject are to be found in medical journals and in the transactions of the learned societies. Dr. Moffatt remarks that myelopathic albumosuria is a new disease—new not in the sense of being the product of hitherto non-existent morbid processes but new by reason of its differentiation by careful clinical observation from other pathological conditions presenting a clinical picture similar in many respects to that of the disease in question. He further truly observes that the number of recorded cases is no trustworthy index of the frequency of its occurrence. When its indications are more generally recognised many more cases will probably be recorded. Such a series of events is by no means uncommon. Actinomycosis was for a long time considered a very rare disease but when the appearance of the pathogenic fungus became better known many cases were placed on record. The same remarks might also be applied to appendicitis and adenoids, conditions which have only been fully understood within comparatively recent years although doubtless they existed long before their true pathology became known.

Dr. Bence Jones was the first observer to draw attention to myelopathic albumosuria and his observations were supplemented by Dr. MacIntyre. Dr. T. R. Bradshaw, however, was the first to diagnose the condition correctly during life and he was the first also to give this name to the disease. The symptoms may be described very briefly. There are pains in the back and sides, increasing weakness, and anæmia, and though there may be temporary remission of the acute symptoms they infallibly recur and progress to a fatal termination. Spontaneous fractures of the ribs have been noted, as also have tumours growing from the ribs and deformity of the dorsal and lumbar vertebræ. Albumose is found in the urine. Of the etiology nothing is known and the chief interest of the disease lies in the pathology and the pathological chemistry. The pathological changes are practically confined to the skeleton, the ribs, the sternum, and the vertebral bodies being always affected. Sometimes alterations have been demonstrated in the pelvic bones and the skull. The long bones have only been found to be diseased in a few cases. The new growth is gelatinous, soft, and vascular. In structure and clinical progress the growth seems to be allied closely to sarcoma but certain differences have been described by Dr. Bradshaw. Particularly interesting is the examination of the urine, as it is only by the detection of "Bence Jones albumose" that the condition can be diagnosed accurately. It is, of course, important to distinguish this albumose from serum albumin and unless the differential analysis between the two is kept clearly in mind errors in diagnosis may easily be made. Dr. Moffatt gives a description of the tests which are to be applied and fortunately they are easy of application and include no elaborate chemical processes. We need not detail the methods here but will refer our readers to the original paper. The source of the proteid body called "Bence Jones albumose" has not yet been definitely ascertained. Three hypotheses have been advanced: (1) That it is derived from the proteid constituents of the food which for some reason fail to undergo normal metabolism; (2) that it is produced by some abnormal metabolism taking place in connexion with the new growth in the bones; and (3) that its production results from some loss of function through the destruction of the bone marrow. Dr. Moffatt quotes observations which have been made in support of the first and second of these propositions but he has not been able to find any record of investigations as to the probability of the third. The matter for the present must remain in abeyance until further work has been accomplished.

Dr. Moffatt has written a valuable *résumé* of what is at present known in regard to the disease. He gives a detailed account of a case which was admitted into Dr. James Barr's wards in the Liverpool

Royal Infirmary and which exhibited the characteristic symptoms and the post-mortem appearances described by other observers. Finally he adds a comprehensive bibliography containing a list (a very considerable one) of writings which have been published on the subject. The communication is thus a very complete one and will doubtless draw attention to a malady which has not been widely recognised. The diagnosis can only be assured by an examination of the urine for certain diseases present symptoms which closely resemble those of myelopathic albumosuria and unless albumose is recognised by the proper chemical tests the true state of affairs may be missed. Amongst such maladies are osteomalacia, muscular rheumatism, spondylitis deformans, and others which are mentioned by Dr. MOFFATT. Now that such a clear account has been given of the principal clinical features of the disease suspicion will be aroused when the symptoms to which we have referred present themselves and we shall await with interest the records of other cases which may from time to time come under observation.

Injuries of the Pancreas.

OF all the many viscera contained within the abdomen none is more securely placed than the pancreas. Although it has not the shelter of the ribs yet between it and the anterior surface of the abdominal wall intervene many important structures. In addition to the anterior wall of the abdomen, there lie in front of the pancreas the small intestine, the transverse colon, the stomach, and the omentum. Still more protected is it from external violence coming from behind, for even if we do not reckon the great vessels, the aorta and the inferior vena cava, there are the second lumbar vertebra with the adjoining portions of the first and third vertebræ in the middle line and the psoas and quadratus lumborum muscles and the thick mass of the erector spinæ laterally, with many fascial strata. The pancreas thus occupies almost the centre of the body and any harmful force coming from without must first encounter other more superficial structures. Yet in spite of its central situation and its very protected position the pancreas is not very rarely wounded. It is true that in a number of the instances which have been recorded the pancreas was only one of several organs which had suffered injury from a severe blow but even in some of these the injury to the pancreas had been greater than that inflicted on the other organs and had in all probability been the immediate cause of a fatal issue. Until comparatively recently it has only been in fatal cases that we have known of any injury to the pancreas, for our knowledge of the physiology of the organ was too rudimentary to enable us to recognise a lesion of the pancreas by the physiological disturbance produced. Even now, indeed, it cannot be said that we are able to recognise by any very definite symptoms that an injury has been inflicted on the pancreas.

When the surgeon's dread of causing peritonitis prevented his operating on the abdomen the only cases of injury to the pancreas recognisable during life were those in which the viscus presented itself at a wound. Thus KLEBURG of Odessa described in 1868 a remarkable case which he had treated. A man, 60 years old, while stooping was wounded in the abdomen with a knife. The wound was horizontal, an inch in length, and was placed midway between the umbilicus and the right costal margin. From it projected a body three inches long, two inches in width, and with a thick free border. It was smooth on the surface and firm in consistence. Percussion showed that the liver was one and a half inches away from the mass, a band of resonance intervening. It was clearly not liver, stomach, bowel, or omentum. As it appeared to be strangulated KLEBURG decided not to attempt to return it, so he fastened the mass to the edges of the wound with sutures and having placed a ligature round the protruded mass he removed it with a knife. On microscopical examination the histological structure was that of pancreatic tissue. Complete recovery followed. In this case a portion of the pancreas was removed without any manifest general disturbance. The whole of the human pancreas has never been removed but the operation has been many times performed on the lower animals and the chief among the effects produced is the appearance of sugar in the urine. There can be little doubt that the same effect would follow complete removal of the gland in man and therefore in this we have a definite sign of the cessation of the function of the pancreas due to injury. A case in many respects similar to that described above has been recorded by LABORDERIE. A little girl, ten years old, while running fell upon an open pocket-knife which inflicted a wound a little below the lower border of the ribs on the right side and the pancreas was found projecting from the wound. An attempt was made to replace the organ but it only succeeded in part and the remainder of the prolapsed viscus was tied and removed with a scalpel. The patient recovered. CALDWELL has also put on record a similar case. A negro was stabbed in the left side and a mass three or four inches long protruded through the wound. This mass became gangrenous and was removed with a knife and on examination it proved to be pancreas. DARGAU has published a case in which the pancreas protruded through a wound between the eleventh and twelfth ribs on the left side. The organ was replaced, the wound was closed, and the patient made a good recovery.

In a case which occurred during the war between the Northern and Southern States of the American Union the opening through which the pancreas protruded was situated on the right side below the ribs. It was encircled with a piece of silver wire which was tightened every day and at last the mass was removed; recovery followed. Many cases of bullet wound of the pancreas have been described and in one instance the patient lived 15 days; the bullet had passed right through the abdominal cavity and had pierced the pancreas but no other organ had been injured. A case of interest and importance is one in which pressure of a tourniquet caused severe bruising of the pancreas. The patient had an aneurysm of the abdominal aorta not far from its bifurcation and an attempt was made to treat this condition by instrumental pressure on the aorta nearer the heart by means of an aorta tourniquet. In the few hours during which the patient survived the application of the instrument no symptoms referable to the pancreas appeared but at the post-mortem examination this organ was found to be much bruised where it lay across the vertebral column. HADRA of San Antonio, Texas, records an interesting case. A boy, nine years old, was riding downhill on a bicycle and was struck in the epigastrium by the handle bar. Faintness and vomiting were present and some hours later he had abdominal pain which was relieved by opiates. Improvement occurred but it was slow and he did not regain his general health. The chief symptom present was an excessive and perverted appetite. About three weeks after the injury a definite swelling appeared in the epigastrium. There was evidently a collection of fluid behind the stomach which stood out in high relief with well-marked borders and the transverse colon could also be defined. The diagnosis made was rupture of the pancreas with leakage into the lesser peritoneal sac. The swelling was incised between the stomach and the transverse colon and about a quart of fluid was evacuated, alkaline in reaction and possessing amylolytic properties. This is probably the mode of origin of many so-called "pancreatic cysts" which follow injury and as the quoted case shows they may be operated on without much difficulty. Surgery, however, has done but little for injury of the pancreas and this is attributable mainly to the fact that it is rare for the pancreas alone to be injured but also to the great depth of the organ and to the usual absence of symptoms indicative of a lesion of the pancreas. So long ago as 1886 SENN prophesied that "the surgery of the future will undoubtedly deal with contusions and lacerations of the pancreas in connexion with visceral injury of some of its adjacent organs. If, in exploring for injuries in this region, the pancreas should be found extensively crushed it would be good surgery to remove the crushed portion after preliminary ligation of the organ on each side of the comminuted portion." In the present issue of THE LANCET is recorded a very noteworthy case in which a man was hit in the abdomen with the pole of a van and when the abdomen was opened by Dr. MARTIN RANDALL a tear of the peritoneum over the pancreas and also a laceration of the substance of the pancreas were found. The torn viscus and the peritoneum were sewn up and a gauze drain was left. After a lengthy convalescence complete recovery followed. Here we see a distinct advance in the surgery of injury of the pancreas. Previously replacement of a prolapsed pancreas or removal of a portion which could not be returned, or drainage of a traumatic cyst or pseudo-cyst, was all that surgery had done for a damaged pancreas. The case is important and marks the commencement of a new epoch in pancreatic surgery, though it is certain that the cases in which surgical intervention will be successful will be few and far between.

KING'S COLLEGE, LONDON.—With a view to prepare the way for the removal of the hospital to Camberwell and the separation of the preliminary and intermediate medical studies the council of King's College has dissolved the medical board and has created a board for advanced medical studies which will superintend the teaching work of the hospital and be organised as a separate department. The preliminary and intermediate studies have been transferred to the Faculty of Science under a separate board.

Annotations.

"Ne quid nimis."

THE HEALTH OF H.R.H. THE PRINCESS VICTORIA.

WE are authorised to make the following statement:—H.R.H. the Princess Victoria developed some time ago—when in her usual good health—evidences of trouble in the appendix. After an attack of influenza early in January these manifestations became more acute and it was considered desirable that the appendix should be removed at as early an opportunity as possible. The operation was simple and without complications and there is every reason to believe that Her Royal Highness will make a good recovery. Sir Francis Laking and Sir Frederick Treves are residing in Buckingham Palace. The nurses are Nurse Fletcher—who nursed His Majesty at the time of his operation—and Nurse Isaacs.

VISIT OF BRITISH PHYSICIANS AND SURGEONS TO PARIS.

THE French physicians and surgeons during their recent visit to London expressed the hope that they would be afforded the opportunity at no distant date of receiving a party of British physicians and surgeons in Paris to visit the hospitals, the science laboratories, and similar institutions, and to discuss further with them matters relating to medical education. To that end a committee was formed in Paris, with Professor Bouchard as president and M. Lucas-Championnière as vice-president, and last December an invitation was received by the London executive committee, of which Sir William Broadbent is chairman. There has been an exchange of views between the Paris and the London committees as to the dates on which it would be most convenient for the visit to take place. After the several possible dates had been discussed it became quite clear that in the opinion of our *confrères* the season of the year most suitable for the visit would be next May. An invitation has now been received from Paris definitely for Thursday, Friday, and Saturday, May 11th, 12th, and 13th, and has been accepted by the London executive committee. A circular letter has been addressed to all those gentlemen who contributed to the fund for the reception of the French visitors last October and they have been requested to inform one of the honorary secretaries (Dr. Dawson Williams, 2, Agar-street, Strand, London, W.C., and Dr. W. Jobson Horne, 27, New Cavendish-street, Portland-place, London, W.) whether they wish to take part in the return visit. At an early date the London executive committee will complete and forward to Paris the list of visitors. It is therefore important that those who have not already replied to the letter should do so without delay. Further particulars of the arrangements will be notified to intending visitors as soon as they are completed.

ROYAL SANITARY INSTITUTE: CONFERENCE ON SCHOOL HYGIENE.

A CONFERENCE on school hygiene will be held in the great hall of the University of London, South Kensington, from Feb. 7th to 10th next, under the auspices of the Royal Sanitary Institute. This conference is intended to pave the way and to prepare the ground for the International Congress on School Hygiene, which is to be held in London in 1907, by discussing some of the aspects of school hygiene which are of pressing importance. Over 100 education committees, colleges, councils, societies, and universities have up to the present appointed delegates, and these, with the members of the Institute, will be welcomed at a reception at 7 P.M.

on Tuesday, Feb. 7th. An hour later Sir Arthur W. Rücker, F.R.S., will deliver the Presidential Address on the Coördination of the Teaching of Hygiene. On Wednesday, Feb. 8th, the subject for the day will be Scholars. This subject will be dealt with under two headings; in the morning that of Physical and Mental Development during School Life and in the afternoon that of Physical Inspection. On Thursday the subject will be Schools, under the headings Building and Equipment and Sanitary Inspection. On Friday the subject will be Training in Hygiene, under the headings Training of Teachers and Training of Scholars. The meetings on Wednesday, Thursday, and Friday will begin at 11 A.M. and 2 P.M. each day. An exhibition of school building and furnishing appliances will be held in the same hall and will be open each day to those attending the conference and to all teachers from 10 A.M. to 6 P.M. and during evening meetings. Fellows, Members, and Associates of the Institute will be supplied with tickets on application and to those not connected with the institute the price of the conference tickets, which are obtainable from the secretary, is 10*s.* 6*d.*

FLANNELETTE.

We have made some tests with the samples which our correspondent has kindly forwarded to us. There is little doubt that the inflammability of the flannelette known as "non-flam" is practically *nil.* After several washings with soap and water, however, there is a tendency of the fabric to regain some of its original inflammable property; but even then this is nothing like so marked as in the untreated flannelette. This behaviour implies that the inflammable flannelette is rendered much less inflammable by treatment with a salt of some kind which after repeated washing of the material is to a large extent removed from it. "Non-flam" at any rate is loaded with mineral matter and according to our experiments this consists largely of a tin salt. We have also received a specimen of the "non-flam" material from the manufacturers which proved to be identical with the piece sent to us by our correspondent. The same correspondent in a further letter points out that in the two recent cases of burning alleged to be due to the use of flannelette the material in the first was a flannelette nightdress and the accident occurred at 9.45 A.M. not P.M. In the second case the child was dressed in flannel and not flannelette, the coroner eliciting from the mother that she had dressed the child in flannel since an attack of bronchitis. The suggestion of our correspondent in favour of the adoption of swinging fireguards seems to us therefore a valuable one and there is much to be said also for the proposal to substitute for the ordinary nightdress for infants a sleeping sack which would prevent the child getting close to the fire. Many children of the poor are probably allowed to play in their nightdresses for the greater part of the day. The fireguard would seem therefore to be the only effectual and practicable remedy against these sad occurrences and we think that the purchasers of flannelette and other inflammable wearing material should be warned about its dangers so that they may take every precaution to prevent the poor little irresponsible infants from exposing their dresses to the risk of ignition.

CURRENT THEORIES OF THE HEREDITARY PROCESS.

IN the third lecture[1] delivered by Professor W. F. R. Weldon, F.R.S., at University College, London, on Dec. 6th, 1904, the question of regeneration of lost parts was dealt with. A planarian worm cut across into two parts forms two entire worms, each half regenerating the missing parts completely. Cut into four parts of equal length, each segment similarly regenerates into a complete animal. Longitudinal splitting of the body into right and left halves results in regeneration of a double-bodied monster with one head. If, however, thin transverse slices are cut off from the middle region of the body a head develops from either cut surface. Such a two-headed monster is unable to feed and dies in a short time. The same occurs when the head of a planarian is cut off. The cut surface regenerates a second head but the dual structure dies shortly after. In the case of the common earthworm, if the anterior three, or even five, segments are cut off the rest of the body will regenerate the lost parts. Here both brain and stomach, which were removed by the operation, are redeveloped—an indication of high regenerative power. On excising the stomach and the ventral nerve cord, after removing the ventral halves of the fourth, fifth, and sixth segments, a new head grew out of the gap, producing an extraordinary double-headed monster. In the case of crustaceans the power of regenerating lost limbs is highly developed. Thus, if the entire leg except the minute pair of proximal segments is broken off a new leg develops from the short stump at the next ecdysis (casting off of the shell). If an eye of a crab is excised there is usually regenerated in its place an antenna (Herbst). This is because the optic ganglion—the immediate centre of regeneration—is removed in such an operation. If, however, the ganglion is situated deeply and is intact at the operation a normal eye is regenerated. The amphibia show, according to their higher position in the animal scale, less power of regeneration. If the eye of the salamander or newt is excised, leaving the posterior choroid intact, a proliferation of cells from the pigment cells of the choroidal margin takes place, forming a new lens—i.e., an imperfect eye. A frog deprived by operation of an upper limb will regenerate one or more abnormal limbs at the site of lesion. The higher vertebrates, and especially the mammalia, have very little power of regenerating lost organs. It is thus shown, concludes Professor Weldon, that the capacity for regeneration, strongly hereditary in the lowest organisms, gradually decreases to a minimum in the highest animals. The influence of environment in determining development is very potent in the case of lower organisms. Maupas and Calkins found that the water in which paramœcium lived for several generations "grew stale" and though well supplied with food the organisms in such an environment eventually became enfeebled and extinct. When the water was entirely changed the enfeebled paramœcia recovered vitality and vigour. The eggs of the sea-urchin can be stimulated to parthenogenetic development by the presence of a large quantity of carbon dioxide in the sea-water, as was shown by Loeb whose experiments were recently confirmed by Delage. The nucleus has been held to be the sole vehicle of heredity by Weismann. Recent experiments of Boveri and Delage have demonstrated that this is incorrect. Both these writers have shown that denucleated eggs produced by mechanical extrusion of nuclei can be fertilised in the sea-urchin and that they give rise to normal blastulæ, gastrulæ, and larvæ. Hence the "determinants" of heredity are present in the cell body of the egg. If such eggs are fertilised by alien spermatozoa (of different sub-species) the larva shows the characters of the male parent, because the "determinants" of these are more potent. It is thus established that hereditary traits are transmissible through both parents and that one parent may be prepotent over the other.

---

[1] Abstracts of the first and second lecture were published in THE LANCET of Jan. 7th (p. 42) and 21st (p. 180), 1905.

THE SAFEGUARDING OF THE PUBLIC BY PRIVATE AGENCIES.

WE note that in a case referred to in another column, under the heading of "Medicine and the Law," after having successfully detected, prosecuted, and obtained the conviction of a man who had sold without complying with the prescribed regulations enough of a dangerous poison to kill 600 people, the Pharmaceutical Society was allowed out of the public funds set aside for such purposes the sum of £1 1*s.* towards its costs. This was after an application made by its advocate who no doubt laid due stress upon the service rendered. We have no desire to minimise such privileges and official recognition as the Pharmaceutical Society may receive in return for services of this kind to the community, nor would we deny that such an agency as, for example, the National Society for the Prevention of Cruelty to Children enjoys a high reputation and is in receipt of considerable funds in return for the good work which it does in the protection of infant life. Many other similar institutions could easily be named, not excluding the Medical Defence Union in its operations directed against illegal practice by quacks, or the Society for the Prevention of Cruelty to Animals which is not concerned with the preservation of human life, all of which, no doubt, do not work without in some degree earning the gratitude of the community. A question, however, may well be raised with regard to institutions concerned with aiding the administration of the law as to whether they do not do too much towards relieving the public authorities of expense and trouble which should rightly be theirs and whether some change would not be desirable, not in the direction of checking the associations referred to in the exercise of their peculiar activities, but rather in that of suitably compensating them for their expenditure and of encouraging the police to more systematic vigilance and more sustained efforts. It is by no means an uncommon occurrence to read at the conclusion of an inquest on some unhappy child who has fallen a victim to the negligence or brutality of his or her parents or guardians that the coroner hopes that the attention of the National Society for the Prevention of Cruelty to Children will be drawn to the case. It would be more satisfactory to learn that the police and the Treasury would promptly do their best to bring to justice persons apparently guilty of crime. We do not forget that certain expenses are allowed to the private agency by the court official who taxes the bill at the conclusion of the trial; but this represents only a portion of the expenditure involved. Where a public agency such as the police is primarily responsible the balance of the cost is paid from another public fund. When the prosecutors are a society composed of private individuals a portion of the expense incurred in enforcing the law of the land is left to be borne by volunteers actuated by benevolent sympathy with suffering. There can also be no doubt that the fact that an association prosecutes which has for its object the punishment of a certain class of crime is likely to some extent to prejudice the case presented against the defendant. "The police, against whom no sinister motive can be suggested, are," as an advocate for the defence might say, "standing aside They have not thought fit to take any steps but their place has been usurped by a society the very existence of which depends upon the number of convictions which it can secure." It is true that such reasoning as this carries no weight with those who are aware of the true state of affairs but it may have its influence with some benches of magistrates and with jurymen. A more or less private body of the nature of those referred to will always have ample scope for its expenditure in exercising a useful form of vigilance and it may be called upon to pay for its own failures. We do not desire to see anything done that would cripple the action of the Pharmaceutical Society in the prevention of illegal dealings in dangerous drugs but we suggest that when an offence against the public safety has been proved to have been committed it is the public purse and funds provided for the enforcement of the law which have to bear the expense.

LUMBAR PUNCTURE IN THE DIAGNOSIS OF MENINGEAL HÆMORRHAGE.

THE use of lumbar puncture in the diagnosis of diseases of the nervous system is a comparatively new procedure. At the meeting of the Société Médicale des Hôpitaux of Paris on Nov. 25th, 1904, M. Letulle and M. Lemierre reported two cases in which this method of examination enabled meningeal hæmorrhage to be diagnosed when it otherwise would not have been. In the first case a woman, aged 20 years, was admitted to hospital on July 21st, 1903. On the previous day after dinner she was suddenly seized with intense headache and vomiting which were soon followed by loss of consciousness. A practitioner who was called in found her comatose and very pale with a slow pulse; the pupils were normal. Suddenly clonic convulsions localised in the left arm and rigidity and contracture of the right arm began. The head was moved about without cessation; the tongue was put out and bitten several times. About 2 A.M. she was rendered quiet by an injection of morphine. The convulsions began again about 4 A.M. but ceased under the influence of an enema of chloral. Before the attack she had enjoyed good health. On admission she was comatose. When her name was called she opened her eyes and looked around and then shut them. The pupils were equal and moderately dilated. The left arm presented some rigidity but was not paralysed. The right arm was strongly contracted and seemed to be paralysed. The knee-jerks were diminished. The respiration was superficial but at times was interrupted by pauses and deep inspirations. The temperature was 100·4° F. and the pulse was 52. The urine did not contain albumin. The diagnosis was thought to lie between uræmia and tuberculous meningitis but lumbar puncture yielded sanguineous cerebro-spinal fluid. On the 22nd the coma persisted and there was profuse perspiration. On the 23rd the patient could respond to simple questions but immediately relapsed into coma. The arms were flaccid and inert. Babinski's sign was obtained but Kernig's was not. There was incontinence of urine and fæces. The morning temperature was 101·5° and the evening 102·2°. The comatose state continued but on the 26th there was delirium. On the 27th a bedsore formed on the buttock. On the 28th there was marked contracture of the arms which were held against the trunk with the forearms flexed and the hands clenched. Death took place on the 30th. At the necropsy on opening the dura mater the frontal lobes were found to be covered with a layer of clotted blood. The base of the brain was also covered by a clot which extended backwards from the longitudinal fissure over the pons and medulla and upwards on to the cerebellum. The fourth ventricle was filled with clot. There was no hæmorrhage in the substance of the brain and the arteries appeared normal everywhere. On opening the spinal dura mater the cord was found to be covered completely with clot which in some places was half a centimetre thick. Microscopic examination of the brain did not reveal the source of the hæmorrhage or anything abnormal. The fluid obtained by lumbar puncture contained 230,000 red and 100 white corpuscles per cubic millimetre. The cause of the hæmorrhage remained undetermined. The absence of Kernig's sign is noteworthy for it is usually present in cases of meningeal hæmorrhage. In the second case the patient was a man, aged 52 years, addicted to alcohol, who was admitted to hospital on April 12th, 1904. On the previous day he returned home drunk, as usual, and was seized with epileptiform convulsions which were followed by coma, in which state he was on admission. There was left hemiplegia; the leg was flaccid, the knee-jerk was absent, and Babinski's sign was obtained. On the right the knee-jerk was also absent but Babinski's sign was not obtained. In both arms some contracture was present. There were conjugate deviation to the right and paralysis of the left side of the face. The temperature was 101·5° and the pulse was 60. The urine did not contain albumin. Lumbar puncture yielded very sanguineous cerebro-spinal fluid which rapidly escaped in drops. It contained red corpuscles, neutrophile polynuclears, some lymphocytes, and some large mononuclears. Abundant cerebral hæmorrhage involving the ventricles was diagnosed. During the night the patient uttered cries and incoherent words. On the 14th he opened his eyes and answered simple questions and the conjugate deviation had almost disappeared. He could move the leg but Babinski's sign persisted. Recovery gradually took place. On the 16th lumbar puncture yielded an orange fluid which on centrifugalisation yielded much less deposit than that previously obtained. On the 18th he could walk but there was still a little facial paralysis and the knee-jerks were absent. In similar cases observed by M. Letulle and M. Lemierre the termination was always fatal although the cerebro-spinal fluid was less sanguineous. The favourable course of this case caused them to alter the diagnosis to that of meningeal hæmorrhage which they thought must have been considerable. The deposit from the cerebro-spinal fluid was much greater than that in the first case. They were of opinion that the lumbar puncture assisted recovery by relieving pressure. The conjugate deviation is noteworthy, for it is rare in meningeal hæmorrhage. It may be suggested that the blood in the cerebro-spinal fluid was due to accidental wounding of a vessel in performing lumbar puncture but this was excluded by the fact that the fluid did not yield clot on standing.

"A MINT IN THE SEA."

WE suggested (correctly as it proves), more than eight years ago, that the announcement that definite quantities of gold had been recovered from sea water would be sure to attract the attention of speculators. The fact that sea water contained gold was first made patent, we believe, by the observation that the deposit on the copper plating of jetty piles in sea harbours was comparatively rich in the precious metal. In an annotation in THE LANCET of Oct. 10th, 1896, p. 1024, under the heading of "A Mint in the Sea," we drew attention to these observations and discussed the possibilities of treating sea water with the view of recovering what must be a vast amount of gold dissolved in it. On the estimate that a ton of sea-water contains approximately one grain the yield would amount to something like 200 tons of gold per cubic mile and as the volume of the world's ocean is estimated at 400,000,000 cubic miles the total possible yield of gold would be no less than 100,000,000,000 tons—a truly attractive prospect to the company promoter. We now learn that a serious attempt is to be made to wrest a proportion, at any rate, of this vast wealth from the sea and that a company is about to start the necessary machinery and plant somewhere on the south coast of England. It should be borne in mind, however, that the original observations as to the sea containing gold were made on the waters which wash the shores of a gold-bearing country—namely, New South Wales. Still, time no doubt suffices to effect a uniform distribution of the mineral salts of the sea, although the composition of sea-water varies with the locality from which it is taken. We should have thought that an eminently practical experiment in this direction would before now have been undertaken by the great steamship companies. Most steamships are equipped with an electric installation and it would be quite an easy matter for them to start a system of electro-plating while at sea without interfering seriously with the progress of the ship. A couple of large copper plates suspended in the sea and connected with the dynamos would serve as electrodes and collect the gold contained in the sea-water during the voyage. At the end of the voyage the plates could be examined for gold and some idea of the practicability of recovering the metal would be gained. If it proved that the steamship companies could add to their equipment an effective electrical gold dredger they might possibly be induced to cheapen the passenger rates according to the success of the system.

IMMUNISATION AGAINST ANTHRAX BY THE USE OF VIRULENT CULTURE.

Mr. J. A. Gilruth, M.R.C.V.S., chief veterinarian and bacteriologist of the New Zealand Government, has made some interesting experiments in guinea-pigs, rabbits, sheep, and pigs to test their immunisation against the bacillus of anthrax when it is inoculated in the body after being mixed with certain other organisms. The experiments were suggested by the observation of peculiar symptoms exhibited by a guinea-pig after inoculation with a small quantity of blood from an animal dead of anthrax, this blood having been accidentally contaminated by another organism during inoculation. As is well known, a guinea-pig or rabbit inoculated even with a small quantity of pure anthrax culture dies within from 24 to 48 hours with comparatively no premonitory symptoms and with no evidence of inflammation at the seat of inoculation. *In this particular case, however,* there was around the region of inoculation for the first two days an intense inflammation which nevertheless produced no disturbance and had disappeared almost entirely on the fifth day after inoculation. The animal was, so far as could be observed, in the best of health, yet on the morning of the sixth day (exactly 140 hours after inoculation) death occurred. A post-mortem examination revealed a typical anthrax condition, the bacillus anthracis being readily demonstrated in enormous numbers in the spleen and other organs. Following up this observation Mr. Gilruth inoculated anthrax bacillus mixed with bacillus coli communis, with streptococcus from a case of human septicæmia, and with bacillus enteritidis (Gaertner) respectively in various proportions. In each case death due to anthrax was delayed much beyond the normal time and in some instances the animals recovered. One rabbit even received within six months five cubic centimetres of anthrax broth culture subcutaneously, half the quantity being injected in a state of purity within a period of nine weeks, thus showing that the mixture of other organisms with that of anthrax considerably delayed the death of the subject. From these and control experiments Mr. Gilruth draws the following conclusions:—

1. Guinea pigs, rabbits, and sheep can completely resist the inoculation of large doses of virulent anthrax bacilli, provided these organisms are mixed with a larger quantity of some other organisms which are [illegible] nmals [illegible] elayed very considerably, when the organism [illegible] bacillus is possessed of small pathogenic properties.

3. The anthrax bacillus must be "mixed" with the other organism, for if they be injected under different parts of the skin no resistance results.

4. An animal which has suffered without absolute impunity the injection of a large dose of anthrax bacillus when mixed with a foreign organism may succumb later to a much smaller dose of anthrax bacillus of pure culture although generally some resistance is evidenced.

5. It was observed with rabbits and sheep which received repeated doses of both anthrax and Gaertner bacillus mixed together in increasing quantities that a certain amount of immunity to comparatively large doses of pure anthrax could be conferred.

THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

THE lectures of the present year to be delivered before the Royal College of Physicians of London are as follows. The Milroy lectures will be given by Dr. T. M. Legge on March 7th, 9th, and 14th, the subject being Industrial Anthrax; the Goulstonian lectures will be given by Dr. W. C. Bosanquet on March 16th, 21st, and 23rd, the subject being Some Considerations on the Nature of Diabetes Mellitus; the Lumleian lectures will be given by Dr. W. H. Allchin on March 28th and 30th and April 4th, the subject being Some Aspects of Malnutrition; and the Oliver-Sharpey lecture will be given by Dr. Leonard E. Hill on April 6th, the subject being the Influence of Atmospheric Pressure on Man. The days of the week for the delivery of the lectures are Tuesdays and Thursdays. The hour of delivery is 5 P.M. at the Royal College of Physicians, Pall Mall East, S.W.

COFFEE AND SEWAGE.

A RATHER strange decision seems to have been arrived at in a case which was concluded at the Southwark police court on Jan. 24th after an adjournment from the preceding week. The application made by the chief sanitary inspector of the borough of Bermondsey was for the destruction of 60 tons of coffee salvaged from a ship which had been sunk in the Thames and the summons was taken out in order to prevent the berries from being dried and sold for human consumption. The evidence of Dr. R. K. Brown, medical officer of health of Bermondsey, of Dr. J. W. H. Eyre, and of Mr. Bodmer was to the effect that the coffee was moist, sodden, permeated with sewage, and unfit for food purposes. Although they admitted that the necessary roasting might modify the dangerous conditions they declined to say that the subsequent decoction would thereby be rendered a wholesome beverage. On the other side, Mr. Friswell of Great Tower-street said that he had drunk coffee made from the sewage-laden berries without untoward results. Dr. F. J. Smith also gave evidence that he was prepared to do the same but that he "would not do so for choice." The magistrate, Mr. C. Chapman, appears to have been satisfied that the usual roasting process was sufficient to render the coffee fit for the food of man and dismissed the application. If he could have ordered that the stuff when sold retail should be labelled "coffee and sewage," so that the purchaser would have the same choice in purchasing that the law gives him in the case of admixture with chicory, the matter might have passed without comment. Few, even when tempted by a cheaper price, would be likely to buy coffee if they knew that it had undergone soaking in the diluted products of the metropolitan drainage system, although the decision of the learned magistrate would seem to be a certificate that 60 tons possibly saturated in varying degrees will make a safe and wholesome drink for those who will partake of it. According to the *Standard* it now appears that Mr. Rose, at Southwark police court, refused to revoke his order for the destruction of the coffee in spite of Mr. Chapman holding with regard to a portion of it that it was fit for human consumption. If this be so we congratulate Mr. Rose on his attitude.

HEREDITARY TRANSMISSION OF SYPHILIS.

ABOUT two years ago Professor Matzenauer, in a paper read before a medical society at Vienna and published in the *Wiener Klinische Wochenschrift*, 1903, Nos. 7-13, stated that in his opinion a direct paternal transmission of syphilis to the offspring has not been proved. His principal conclusions may be summed up in three general propositions: first, "that the mother of a congenitally syphilitic infant is invariably herself the subject of syphilis, even when to all appearances healthy." The second is "that an inheritance of the disease through an infected ovum or spermatozoon—that is, hereditary transmission in the true sense of the word—has not been proved." The third proposition is the natural consequence of these—viz., that the infection of the offspring is in every case secondary and brought about by an infection from the mother by the channel of the placental circulation. If these be accepted it follows that what has been called *choc en retour*, that is, the infection of a healthy mother through the placental circulation by a syphilitic fœtus, the result of paternal infection, does not exist. From the outset these conclusions of Professor Matzenauer were vigorously attacked and a somewhat polemical discussion raged in certain German and Austrian papers for some time. A paper has been published in the *Munchener Medicinische Wochenschrift*, Nos. 49 and 50, 1904, by Dr. Jesionek of Munich, in which two cases of considerable interest are recorded and Professor Matzenauer's views are vigorously criticised. The first case was that of a girl, aged 18 years, admitted into hospital for an attack of gonorrhœa, the gonococci being repeatedly demonstrated in the discharge. Since the case was one brought in by the police and was being dealt with judicially very careful examination was repeatedly made by several observers for evidence of syphilitic affection but always with negative result. It soon became apparent that the patient was pregnant and about four months after the date of impregnation her general condition, which had previously been good, markedly deteriorated and about a month later she developed a typical severe syphilitic roseolous eruption. The patient had been in hospital during the whole of this time and no evidence could be found of any primary chancre or anything to point to infection while in hospital. Shortly afterwards general enlargement of lymphatic glands became manifest and the case progressed as an ordinary case of secondary syphilis. About two and a half months later—that is, about the middle of the eighth month of pregnancy—a dead fœtus 35 centimetres in length was born which showed appearances typical of congenital syphilis—viz., maceration, enlarged spleen, swelling and parenchymatous degeneration of the liver, general icterus, syphilitic osteochondritis, multiple hæmorrhages, and complete atelectasis. Dr. Jesionek considers it highly improbable that such advanced changes as were found in almost all the organs of the fœtus could have developed in the short space of two and a half months, and taking into consideration the history of the case comes to the conclusion that the case is one of *choc en retour* and that infection of the fœtus through the spermatozoon without direct infection of the mother is thus a possibility. He also brings forward another case in support of his contention that the spermatozoa may serve as [illegible] 45 years, who acquired a primary chancre on one of his right fingers from attending a syphilitic woman in her confinement; this was followed by a typical rash and sore-throat. Treatment by mercurial inunction was adopted vigorously for four months, after which period no signs of syphilis were discoverable. Shortly afterwards the patient resumed conjugal relations with his wife who subsequently developed a chancre of the vagina followed by roseola and glandular enlargements. In this case Dr. Jesionek attributes the infection to the spermatozoa since no syphilitic lesions such as mucous patches or a rash could be found about the man. Although no generalisations can be made from two cases yet the very careful manner in which they have been observed and recorded demands that due attention shall be given to the conclusions to which they apparently point, and while we cannot on this evidence alone accept Dr. Jesionek's conclusions that the spermatozoa of a syphilitic man are directly infective and that paternal inheritance and *choc en retour* are both proved, yet the striking nature of the cases should lead to careful observation of others in the same manner by other observers, and the paper forms a valuable addition to our knowledge of a controversial matter.

DINNER AND DISEASE.

IN an evening contemporary there recently appeared an admirable article by Mrs. Hugh Bell entitled "The Dietetics of Conversation." In it she protests against the perpetual references to health, disease, and the state of the "inside" which now form such a prominent topic of conversation. In her own words: "To have people sitting in one's drawing-room talking about their secretions seems to me repellent, not to say disgusting. It is bad enough to have each of their most trifling actions explained and justified by a symptom; but it is quite intolerable that each symptom should in its turn be explained and a name given to the particular form of acid or of inflammation to which it is due." Further on she says: "It is like poor people, whose favourite form of conversation is to offer to show you their 'bad leg'—a mysterious disease which will no doubt in due time work its way up into the drawing-rooms and the conversation of Belgravia." We quite agree with Mrs. Hugh Bell but we do not think that the style of conversation to which she objects is altogether a novelty. In chapter 41 of that storehouse of human psychology, "Vanity Fair," Thackeray refers to Lady Jane Crawley and Becky Sharp having one of those confidential medical conversations about the children which all mothers delight in. He continues, with a fine disregard of dates,[1] "Fifty years ago, and when the present writer, being an interesting little boy, was ordered out of the room with the ladies after dinner, I remember quite well that their talk was chiefly about their ailments." Again, in chapter 60, after an account of one of Joseph Sedley's dinner parties, we learn "Politics stepped in a short time after dessert when the ladies retired upstairs and talked about their complaints and their children." Nowadays, however, the talk about complaints is openly indulged in at the dinner-table by members of opposite sexes and in our opinion it is due in great part to that emancipation for which women have been crying out for so long and which now they have undoubtedly gained. Not only have we heard appendicitis discussed at the dinner-table but even intimate gynæcological complaints. It is true that London society is not yet so advanced as is fashionable society in Paris, for the records of a recent trial have shown that there an occasional entertainment is a biograph representation of the hostess or one of her friends undergoing an abdominal section. But it is too true that refinement and that old-fashioned virtue known as reserve have markedly decreased of late years. The arcana of feminine dress are exposed to all and sundry in every shop window, to say nothing of the advertisements in fashion papers, and although there is nothing immoral in underclothing or in conversation about appendicitis or curetting we cordially agree with Mrs. Hugh Bell that such matters are not fitting for ordinary social conversation.

CEREBRAL HÆMORRHAGE IN CHILDREN.

IN another column we publish an interesting case of non-traumatic cerebral hæmorrhage in a child, aged ten years, recorded by Dr. Hugh Taylor. Cerebral hæmorrhage in children is certainly a rare disease but nevertheless it has to be borne in mind in ascertaining the cause of sudden or unforeseen death in young subjects. It may be meningeal or intra-arachnoid or into the substance of the brain, the first-named being the more common. Meningeal hæmorrhage is generally met with in children at the period of dentition. At this time congestive attacks may occur, including lesions of the parietal arachnoid which becomes vascular; the small vessels newly formed in the membranes may burst and sudden death follows. Whooping-cough may also be the cause of the hæmorrhage or severe purpura may bring it about. Thrombosis of the sinuses and the various abnormal conditions of the blood met with in the exanthemata are also occasional causes. Hæmorrhage into the substance of the brain seldom occurs in children; when it is found it has in most cases been secondary to ulcerative endocarditis and has been due to embolism Very exceptionally the vessels in childhood present a condition of atheroma and cerebral hæmorrhage has resulted from the rupture of a vessel thus diseased. Congenital syphilis may also produce vascular lesions in the brain and elsewhere. Dr. Taylor states that in his case all the other organs were macroscopically quite healthy. Probably some disease of the blood-vessels of the brain was present which would only have been detected on microscopic examination.

INFLUENZA AND ENDOCARDITIS.

SINCE influenza has established itself as a permanent scourge in this country we have had only too frequent opportunities of observing the disturbing effects of its toxins upon the heart. The most common manifestations of this action are seen in the irregularities characteristic of the pulse in influenza; this may be frequent, infrequent or irregular, or may exhibit the special "instability" described by Huchard. These disturbances must in all probability be ascribed to the action of the poison of influenza upon the nervous apparatus of the heart. But actual inflammatory affections of the organ may also occur and both pericarditis and endocarditis are sometimes met with, though they are comparatively rare. A case of the latter affection has recently been recorded by Dr. Pedro Escudero in a communication made to the Argentine Medical Society.[1] The patient was a boy, aged 13 years, who went through an attack of influenza complicated by pneumonia affecting both lungs in succession. The pneumonia resolved satisfactorily but a relapse of fever occurred, accompanied this time by the appearance of a systolic murmur at the apex of the heart, conducted into the axilla. This persisted after convalescence and apparently pointed to an organic valvular lesion. There is some doubt as to control experiments Mr. Gilruth draws the following conclusions:—

---

[1] "Vanity Fair" was written in 1847-48 and Thackeray was born in 1811.

[1] "Endocardite Grippale," Argentina Medica, Nov. 19th, 1904.

1. Guinea-pigs, rabbits, and sheep can completely resist the inoculation of large doses of virulent anthrax bacilli, provided these organisms are mixed with a larger quantity of some other organisms which are non-pathogenic to these animals.

2. Death is frequently delayed very considerably when the organism mixed with the anthrax bacillus is possessed of small pathogenic properties.

3. The anthrax bacillus must be "mixed" with the other organism, for if they be injected under different parts of the skin no resistance results.

4. An animal which has [illegible] the injection of a large dose of [illegible] ign organism may succumb l[illegible] rax bacillus of pure culture although generally some resistance is evidenced.

5. It was observed with rabbits and sheep which received repeated doses of both anthrax and Gaertner bacillus mixed together in increasing quantities that a certain amount of immunity to comparatively [illegible] could be conferred.

[illegible] may possibly afford a surer [illegible] immunity against anthrax, [illegible] in vogue.

THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

THE lectures of the present year to be delivered before the Royal College of Physicians of London are as follows. The Milroy lectures will be given by Dr. T. M. Legge on March 7th, 9th, and 14th, the subject being Industrial Anthrax; the Goulstonian lectures will be given by Dr. W. C. Bosanquet on March 16th, 21st, and 23rd, the subject being Some Considerations on the Nature of Diabetes Mellitus; the Lumleian lectures will be given by Dr. W. H. Allchin on March 28th and 30th and April 4th, the subject being Some Aspects of Malnutrition; and the Oliver-Sharpey lecture will be given by Dr. Leonard E. Hill on April 6th, the subject being the Influence of Atmospheric Pressure on Man. The days of the week for the delivery of the lectures are Tuesdays and Thursdays. The hour of delivery is 5 P.M. at the Royal College of Physicians, Pall Mall East, S.W.

COFFEE AND SEWAGE.

A RATHER strange decision seems to have been arrived at in a case which was concluded at the Southwark police court on Jan. 24th after an adjournment from the preceding week. The application made by the chief sanitary inspector of the borough of Bermondsey was for the destruction of 60 tons of coffee salvaged from a ship which had been sunk in the Thames and the summons was taken out in order to prevent the berries from being dried and sold for human consumption. The evidence of Dr. R. K. Brown, medical officer of health of Bermondsey, of Dr. J. W. H. Eyre, and of Mr. Bodmer was to the effect that the coffee was moist, sodden, permeated with sewage, and unfit for food purposes. Although they admitted that the necessary roasting might modify the dangerous conditions they declined to say that the subsequent decoction would thereby be rendered a wholesome beverage. On the other side, Mr. Friswell of Great Tower-street said that he had drunk coffee made from the sewage-laden berries without untoward results. Dr. F. J. Smith also gave evidence that he was prepared to do the same but that he "would not do so for choice." The magistrate, Mr. C. Chapman, appears to have been satisfied that the usual roasting process was sufficient to render the coffee fit for the food of man and dismissed the application. If he could have ordered that the stuff when sold retail should be labelled "coffee and sewage," so that the purchaser would have the same choice in purchasing that the law gives him in the case of admixture with chicory, the matter might have passed without comment. Few, even when tempted by a cheaper price, would be likely to buy coffee if they knew that it had undergone soaking in the diluted products of the metropolitan drainage system, although the decision of the learned magistrate would seem to be a certificate that 60 tons possibly saturated in varying degrees will make a safe and wholesome drink for those who will partake of it. According to the *Standard* it now appears that Mr. Rose, at Southwark police court, refused to revoke his order for the destruction of the coffee in spite of Mr. Chapman holding with regard to a portion of it that it was fit for human consumption. If this be so we congratulate Mr. Rose on his attitude.

HEREDITARY TRANSMISSION OF SYPHILIS.

ABOUT two years ago Professor Matzenauer, in a paper read before a medical society at Vienna and published in the *Wiener Klinische Wochenschrift*, 1903, Nos. 7–13, stated that in his opinion a direct paternal transmission of syphilis to the offspring has not been proved. His principal conclusions may be summed up in three general propositions: first, "that the mother of a congenitally syphilitic infant is invariably herself the subject of syphilis, even when to all appearances healthy." The second is "that an inheritance of the disease through an infected ovum or spermatozoon—that is, hereditary transmission in the true sense of the word—has not been proved." The third proposition is the natural consequence of these—viz., that the infection of the offspring is in every case secondary and brought about by an infection from the mother by the channel of the placental circulation. If these be accepted it follows that what has been called *choc en retour*, that is, the infection of a healthy mother through the placental circulation by a syphilitic fœtus, the result of paternal infection, does not exist. From the outset these conclusions of Professor Matzenauer were vigorously attacked and a somewhat polemical discussion raged in certain German and Austrian papers for some time. A paper has been published in the *Munchener Medicinische Wochenschrift*, Nos. 49 and 50, 1904, by Dr. Jesionek of Munich, in which two cases of considerable interest are recorded and Professor Matzenauer's views are vigorously criticised. The first case was that of a girl, aged 18 years, admitted into hospital for an attack of gonorrhœa, the gonococci being repeatedly demonstrated in the discharge. Since the case was one brought in by the police and was being dealt with judicially very careful examination was repeatedly made by several observers for evidence of syphilitic affection but always with negative result. It soon became apparent that the patient was pregnant and about four months after the date of impregnation her general condition, which had previously been good, markedly deteriorated and about a month later she developed a typical severe syphilitic roseolous eruption. The patient had been in hospital during the whole of this time and no evidence could be found of any primary chancre or anything to point to infection while in hospital. Shortly afterwards general enlargement of lymphatic glands became manifest and the case progressed as an ordinary case of secondary syphilis. About two and a half months later—that is, about the middle of the eighth month of pregnancy—a dead fœtus 35 centimetres in length was born which showed appearances typical of congenital syphilis—viz., maceration, enlarged spleen, swelling and parenchymatous degeneration of the liver, general icterus, syphilitic osteochondritis, multiple hæmorrhages, and complete atelectasis. Dr. Jesionek considers it highly improbable that such advanced changes as were found in almost all the organs of the fœtus could have developed in the short space of two and a half months, and taking into consideration the history of the case comes to the conclusion that the case is one of *choc en retour* and that infection of the fœtus through the spermatozoon without direct infection of the mother is thus a possibility. He also brings forward another case in support of his contention that the spermatozoa may serve as the honorary secretary, Dr. David Walsh, 18A, Hanover-street, London, W. All who hold the diploma of a Scotch college are invited to attend, whether they are members of the association or not.

AT a meeting of the Hospitals Association which will be held on Friday, March 3rd (by the permission of the council of the hospital), in the hall of Charing Cross Hospital, Mr. D. G. Mackintosh, medical superintendent of the Western Infirmary, Glasgow, will read a paper on the Control of Hospital Expenditure with Efficiency. Tickets of admission may be obtained on application to the honorary secretary of the association at 28, Southampton-street, Strand, W.C.

THE opening lecture of the winter session of 1905 at the *Hospital for Consumption and Diseases of the Chest*, Brompton, S.W., will be delivered by Dr. H. Batty Shaw on Wednesday, Feb. 8th, at 4 P.M., on the Selection of Cases of Tuberculosis of the Lungs suitable for Treatment by means of the Tuberculins and other Specific Agents. The lectures are free to all qualified medical practitioners and to students of medicine.

THE Lettsomian lectures of the Medical Society of London will be delivered by Dr. G. H. Savage on Feb. 6th and 20th and March 6th. The subject of the first lecture is Functional Mental Disorders; of the second lecture, Toxic Mental Disorders; and of the third, Mental Disorders of Decay. The lectures will be delivered at the rooms of the society, 11, Chandos-street, Cavendish-square, and they will commence at 9 P.M.

AN address on the Physical Advantages of Universal Naval and Military Training will be given by Lieutenant-Colonel). T. Duke, until lately honorary secretary of the Lads' Drill Association, at the Caxton Hall, Westminster, at 5.30 P.M., on Tuesday, Feb. 7th; Sir William S. Church, Bart., will take the chair. Baron Suyematsu, late Minister of the Interior for Japan, will also speak.

THE annual general meeting of the Neurological Society of he United Kingdom will be held at 11, Chandos-street, ondon, W., on Thursday, Feb. 16th, at 8.30 P.M. Sir John atty Tuke, M.P., will deliver the presidential address on he Relation of the Lunacy Laws to the Treatment of nsanity.

A GENERAL meeting of the Society for Psychical Research ill be held at 20, Hanover-square, London, W., on Monday, eb. 6th, at 8.30 P.M. Professor Charles Richet will deliver presidential address.

THE ARMY MEDICAL SERVICE OF THE ARGENTINE REPUBLIC.

BY F. HOWARD, M.D. ST. AND.,
COLONEL, ARMY MEDICAL STAFF (RETIRED).

THE corps of military surgeons directs the sanitary service [illegible] the army, under the superior chief of the forces, holding enary power and following the authorised procedures in ormal and urgent cases under the orders of the commandant-in-chief. The sanitary service consists of surgeons, pothecaries, and veterinary officers and is divided into (a) the General Inspectorate; (b) the service in the different actical units which form the army—viz., army corps, [illegible] egiments; and (c) service in the [illegible] military training establishments. [illegible] te is comprised of the director of e sanitary corps and a board called "Inspecsion General," mposed of the inspector-general, president; surgeons of the army, inspecting apothecary, and inspecting veterinarians, members; a surgeon acting as secretary. The inspector-general has under his orders the *personnel* of his office and is recognised as a general of brigade enjoying all corresponding honours, &c., of that rank. The duty of the inspector-general is to supervise the sanitary service of the whole army, to inquire into the complaints of military chiefs and surgeons, to give account of the results of special commissions of a technical nature whether medical or pharmaceutical, to disburse accounts, to keep a record of punishments, and to furnish annually to the military chief the works done by the sanitary corps. To the office of the inspector-general are allowed a secretary, an accountant, an assistant, two clerks, and one orderly.

In peace the service of the corps is worked by surgeons of corps, of regiments, of brigades, and divisions, and by apothecaries of the first and second class. In war the service is divided into administrative (direction) and executive. The former is in the hands of an army [illegible] division, brigade, and [illegible] rform their duties in [illegible]

The surgeon of the army corps has under his immediate orders the sanitary *personnel*, hospitals, and ambulances allotted to each corps. In time of war the director of the sanitary service has authority over officers and men of the sanitary corps, submitting to the chief of the army his requirements for increase of *personnel* or *matériel*. He has the right of punishing officers serving under him and furnishing reports thereon. He has also the direction of the hospitals of aid societies. He is responsible to the commandant-in-chief of the army and to the inspector-general of the sanitary service. The surgeons of division direct the sanitary service of their respective divisions, having charge of the hospitals and ambulances. They are under the orders of the chief of the division and report all matters pertaining to sanitation, &c., to the inspector-general. They keep statistics of hospitals and carry out meteorological and climatic observations, studying the flora and fauna and geographical conditions of the locality in which they may serve. These divisional surgeons have the rank of lieutenant-colonel in the army and enjoy all the prerogatives of that rank. The surgeons of brigades rank as majors and are under the orders of the chief of the brigade. The brigade hospitals and ambulances and the *personnel* and *matériel* are under their orders. The surgeons of regiments have the rank of captains. They have charge of the nursing department of the army, instructing nurses and bearers, vaccinating the troops, and supervising *personnel* and *matériel*. The younger surgeons rank is that of first lieutenant. The duty of these officers consists of daily inspection of the sick, inspection of the food-supply and cooking, investigation of the water-supply, and sanitation generally. Each regiment has one medical officer, one apothecary, and one sick attendant, and arrangements exist to permit of a great number of sick being treated without going to hospital.

The apothecary corps has for its *personnel* one inspecting apothecary, one principal apothecary of the army, and apothecaries of the first and second class. They enjoy prerogatives of rank the same as surgeons. They are responsible for the upkeep of pharmaceutical and chemical stores, for compounding prescriptions, &c. The inspecting apothecary is the chief of his branch under the inspector-general of the Sanitary Service. The principal apothecary of the army is the second head. The apothecaries assist generally in the hospitals and infirmaries in peace, and in war in the camp hospitals and ambulances. The veterinarians have the care of all animals and, in particular, horses. The nursing orderlies serving under the surgeons are divided into first-class, sergeants; second-class, corporals; and third-class, privates.

The *personnel* of each hospital consists of (*a*) a medical officer, director; (*b*) surgeons, apothecaries, and assistants; (*c*) one nursing orderly for 12 sick, when there are sisters of charity, with power to increase the number; and (*d*) servants (civil) who assist the medical staff. The direction of the military hospital in the capital is in the hands of an army surgeon. The administration of military hospitals is under the immediate supervision of the General Inspection Board, to which allusion has already been made in the beginning of this article.

The central laboratory and drug stores are likewise under the superintendence of the General Inspection Board, while the director is the apothecary inspector, the sub-director the principal apothecary, the further *personnel* being two apothecaries, first class, and two assistant apothecaries. The subordinate staff is fixed by the director who supervises the drugs and laboratory, keeps records of purchases and disbursements and current accounts with each hospital, informs the General Inspection Board of requirements, nominates employés, removes those unfit, and finally submits a monthly and an annual report of all going on under his direction. The sub-director personally superintends the work in the laboratories; he keeps books, in one of which he notes the dates of all the preparations made, in another the outgoings, and in a third, with counterfoils, all articles disbursed at the central drug store. He has charge of the meteorological observations, teaches the army apothecaries analytical work, and is responsible for the contents of the laboratory, reporting monthly and annually to the director all matters connected with it. There is a so-called "surgical arsenal" where all instruments, remedies, disinfectants, and all necessaries for the operating room are kept. There is a central depôt of articles for hospital use and sanitary war *matériel.** The administrative officials are divided into cashier, official accountant, and storekeeper, with their attendants, servants, and others.

Military Medical School.—A decree of the President of the Argentine Republic, dated May 24th, 1902, created a military medical school for the theoretical and practical instruction of students of the faculty of the Republic who may desire to be surgeons, apothecaries, and veterinarians in the army. This school is dependent on the General Inspection Board (of Health) of the Army and is under the care of an army surgeon as chief and director of studies. There are certain conditions as to the selection of students but this fact has to be noted particularly—viz., that the entire expense from the entry of the students into the school to the end of the course is defrayed by the State. The number of students is fixed annually and depends on service requirements. It is needless to go into details as to the plan of studies for the different classes of students, suffice it to say it embraces military surgery, pathology, chemistry, bacteriology, hygiene, and so on. The two most distinguished students are entitled to a journey to Europe for one year to complete their studies at Government expense. Students who fail to give satisfaction are discharged, without power to return, and are subject to the condition of having to serve as soldiers. The professors at the school are surgeons, apothecaries, and veterinary surgeons of the army. The *personnel* of the school is composed of a chief and director of studies, professors, tutors, and assistants. The monthly emoluments over and above salaries (in the case of professors) are as follows. (The Argentine dollar may be roughly taken as 1*s.* 10*d.* of our money.)

Chief and Director	$150
Professors of surgery, medicine, pathology, bacteriology, hygiene, and medico legal subjects ..	$100 each
Professors of pharmacy and veterinary medicine and surgery	$80 ,,
Medical students of sixth and seventh years	$40 ,,
,, ,, of fifth, fourth, and third years ...	$30 ,,
Veterinary students	$25 ,,
Apothecary students	$20 ,,

The Central Military Hospital.—The military authorities have created as a crowning point of their army medical organisation the central military hospital at Buenos Ayres, which is described as a splendid establishment and undoubtedly the first of its kind in South America. It was completed in 1888 at a cost, including site and building, of upwards of $1,000,000 of the national currency. The description of it would require several columns. Sufficient to say that there are complete installations for hydrotherapy and massage, anatomical, chemical, bacteriological, and radiographical, &c., services. It is completely surrounded by lines and cross-lines of electricity and drainage connecting it with the arsenal of war and the other municipal hospitals. For complete information I refer readers to the *Anales de Sanidad Militar* for May, 1903, published at Buenos Ayres.

ROYAL EAR HOSPITAL, SOHO.—Lectures which are free to medical practitioners are given at this hospital in Dean-street, Soho, every Thursday at 5 o'clock. Further particulars may be obtained from Mr. P. Macleod Yearsley, honorary secretary of the medical board.

TWELFTH ANNUAL REPORT (FOR 1903) OF THE MEDICAL OFFICER OF HEALTH OF THE ADMINISTRATIVE COUNTY OF LONDON.

(*Concluded from p. 248.*)

IT is matter for regret that limitations of space preclude our commenting in THE LANCET on Sir Shirley F. Murphy's statistics regarding several diseases other than those which we have already noticed but which are of considerable importance from a preventive point of view. The diseases known as erysipelas, puerperal fever, influenza, and pneumonia, which annually destroy many lives, are carefully passed in review in the report, especially with regard to their several rates of incidence or of fatality and the relation thereto of locality, age, and sex, but for detailed information concerning these diseases reference must be made to the report itself. With respect, however, to two of the diseases not previously noticed—pulmonary tuberculosis and cancer—our readers will naturally expect some comment, for these diseases are responsible for a large portion of the total mortality in the metropolis. In regard to the fatality from pulmonary tuberculosis in London we are informed that from the earliest years respecting which trustworthy information exists there has been a steady decline similar to that obtaining in most other parts of England. During the ten years 1851-60 this disease was fatal in London to 286 out of every 100,000 persons living, but in 1903 the proportion had fallen to 160 in the same number living. Quite exceptionally, as far as we know, the deaths occurring in public institutions in, or belonging to, London have been distributed to the areas from which the patients originally came; it is, therefore, practicable to compare the metropolitan boroughs with respect to their death-rates. In the present report a table appears giving these rates after correction by the use of appropriate factors, the latter being calculated by applying the population of the metropolitan boroughs severally to the general London rates at each age and of each sex in the five years 1897–1901. The table shows that in proportion to population pulmonary tuberculosis was most fatal in the metropolitan borough of Holborn where the mortality was in excess of the mean rate by 78 per cent., it was least fatal in Hampstead where the proportion did not exceed 47 per cent. of the mean. The first and last quarters of the year constitute the period of highest fatality from this disease, the second and third quarters being relatively less fatal.

The system of voluntary notification of pulmonary tuberculosis has been adopted by more than half of the metropolitan boroughs, the council of the borough of Holborn, which at present suffers exceptionally from that disease, having decided in the course of 1903 to adopt this measure for limiting its spread. Among other measures complementary to notification careful inquiries are made by the several authorities into the supposed source of infection and into the family history of the patient. These measures are, of course, supplementary to the ordinary methods of sanitation and their success will depend on the degree in which they are regarded as such rather than as substitutes for such elementary but essential precautions. In the course of 1903 the by-law of the London County Council having for its object the prevention of infection by tubercle came into force. This by-law provides that "no person shall spit on the floor, side, or wall of any public carriage or any public hall, public waiting-room, or place of public entertainment, whether admission thereto be obtained upon payment or not." The penalty attaching to breach of this by-law is 40*s.* and it is important to note that the enforcement of this penalty can be secured by anyone who has witnessed the practice against which the by-law is directed. The words "any public carriage" include a railway carriage.

With reference to cancer we learn from the report that owing to changes of area in the sanitary districts of London effected by the London Government Act of 1899 the death-rates since 1900 are [illegible] [illegible]tive purposes. We find, [illegible] 's decennial supplement that in the years 1881–90 London occupied among English counties the highest position in the scale of cancer fatality, and this after making the fullest allowance for age and sex differences of the populations.

Sir Shirley Murphy's figures show that the London deaths from cancer are still increasing in number, the mortality in the last three years having been equal to 93, 99, and 102 respectively in each 100,000 persons living. An interesting table appears in the report showing the incidence of cancer mortality on the several metropolitan boroughs since 1900, [illegible] possible by dis- [illegible] had previously [illegible] public institu- [illegible] of only three years is perhaps too limited to justify other than very [illegible] to which the com- [illegible] two columns of the [illegible] But if the figures are to be trusted they show that the boroughs of Marylebone and Hampstead sustained the greatest loss of life by cancer in 1903 and the borough of Greenwich the least.

In the second part of his report Sir Shirley Murphy discusses several matters relative to the administrative work of his department during the year 1903. Constant and careful supervision has, as in previous years, been maintained with regard to the prevalence of nuisances and to the regulation of offensive businesses and of common lodging houses.

Under the Housing of the Working Classes Act several representations have been made and schemes undertaken, either by the County Council on its own initiative or by the borough councils with the County Council's approval, under Parts I., II., and III. of that Act, the details of which, both as regards the demolition of property unfit for human habitation and as regards the erection of new dwellings, are fully given in the report. The administration of the Factory and Workshops Act has received due attention at the hands of [illegible] have the inspec- [illegible] night shelters, [illegible] urphy's remarks [illegible] general super- [illegible] and its purity, will, it is hoped, be brought into much closer relation than at present with the public health department of the County Council. The serious warnings of Dr. T. E. Thorpe, the official water examiner, as regards the necessity for further precautions in the filtration, the storage, and the distribution of drinking water are of vital importance to the vast population which depends for its very existence on its purity and quantitative sufficiency. We trust that his weighty words respecting the condition of the water-supply and the floods in the Thames Valley in June and October respectively will receive the attention which their great importance demands.

Turning now to the appendices, which occupy almost half of the medical officer's report, we note that Dr. W. H. Hamer's report on the prevalence of enteric fever in London is there reprinted. This interesting document, which we reviewed fully in THE LANCET of July 23rd, 1904, p 233, connects the spread of enteric fever with the eating of imperfectly cleansed and insufficiently fried fish in certain extensive districts of the metropolis. Sir Shirley Murphy does well to keep this important topic constantly before the authorities concerned, for fried fish is very largely consumed in many of the poorer districts of London as the chief article of food, and Dr. Hamer has abundantly shown that little care is ordinarily devoted to its preparation for that purpose. The second appendix contains a report by Dr. C. W. F. Young, the recently appointed county medical officer of health of Middlesex, with respect to the sanitary appointments of the tenement dwellings of London. In the course of 1903 Dr. Young inspected a large number of [illegible] which now consist [illegible] dently been intende [illegible] lies, in order to asce [illegible] could [illegible] ealth [illegible] In [illegible] ound [illegible] l by one family, except in so far as relates to water-closet accommodation which has been increased in order to comply after a fashion with the minimum regulations of the County Council made under the London Public Health Act. Even in the important matter of water-supply no alteration has been made on a scale sufficient for the requirements of the inmates of sublet houses. The only available water tap appears to be placed usually in the backyard or in the washhouse on the ground or basement floors. The result of these inconveniences is that drinking water is often stored in receptacles within each tenement and that waste water and household slops, which ought speedily to be removed, are also there retained, thus seriously endangering the wholesomeness of the dwellings. The report gives an account of an inquiry as to the accommodation provided in the ordinary tenement house for the cooking of food and this Dr. Young finds to be generally unsatisfactory. In at least one-third of between 700 and 800 tenements inspected in the course of the year no oven existed in which food could be cooked, the fire-grate being the same as that provided when the house was originally built and not better adapted than an ordinary bedroom grate for cooking purposes. In a certain proportion of tenements gas stoves were supplied for cooking purposes but these were fitted with so little care that Dr. Young states that no provision whatever had been made for carrying off the products of combustion. For hot water the tenants have ordinarily to depend on the use of a kettle. In a small number of instances a boiler was found in connexion with the fire-grate but almost invariably this was defective and out of use. In the tenements visited no special provision existed for the storage either of food or of fuel. In Dr. Young's opinion the conditions chiefly calling for remedy are the provision of a more accessible water-supply for each tenement and the construction of a suitable place for each tenement in which food can be properly kept. It is questionable whether in addition each tenement should not be provided with a cooking stove. This, [illegible] that [illegible] poorer neighbourhoods so that the provision of this convenience cannot be urged with the same force as in the case of water-supply and storage of food.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

A COMITIA was held on Jan. 26th, Sir WILLIAM SELBY CHURCH, Bart, K.C.B., the President, being in the chair.

The PRESIDENT announced that the subject of the Bradshaw lecture, to be delivered by Dr. G. R. Murray, would be Exophthalmic Goitre.

The following gentlemen having passed the required examination were elected as Members of the College: Henry Willoughby Gardner, M.D. Lond., L.R.C.P. Lond.; Charles John Nepean Longridge, M.D. Vict., L.R.C.P. Lond; and William Henry Willcox, M.D. Lond.

Licences to practise physic were granted to 101 gentlemen who had passed the required examination.

Diplomas in Public Health were granted jointly with the R[illegible] of England to the following ge[illegible] Bankart, M.B., C.M. Edin.; Jo[illegible] Glasg.; George Alfred Edsell, M.D. Durh., L.R.C.P. Lond., M.R.C.S. Eng., L.S.A.; William Lloyd Edwards, L.R.C.P. Lond., M.R.C.S. Eng.; Edward Haines, L.R.C.P. Lond., M.R.C.S. Eng.; Oswald Horrocks, L.M. & S. Madras, L.R.C.P., F.R.C.S. Edin.; Major Oliver Richard Archer Julian, R.A.M.C., L.R.C.P. Lond., M.R.C.S. Eng., L.S.A.; Surgeon-Major Charles Randolph Kilkelly, M.B., B.Ch. Dub., L.R.C.S. Irel.; Frederick Norton Menzies, M.D., B.S. Edin., M.R.C.P. Edin.; Robert Macfarlane Mitchell, M.B., Ch.B. Edin., F.R.C.S. Edin.; *Captain Arthur Hugh Morris*, R.A.M.C., L.R.C.P. Lond., M.R.C.S. Eng.; Major Albert Pearse, R.A.M.C., L.R.C.P. Lond., M.R.C.S. Eng.; John Richards, L.R.C.P. Lond., M.R.C.S. Eng.; Frank Edward Scrase, [illegible] ghtman Sinclair, [illegible]; Robert Small, [illegible] rederick Robert Elliston Wright, M.B. Lond., L.R.C.P. Lond., M.R.C.S. Eng.

The PRESIDENT announced that Dr. W. Heaton Hamer had been appointed as Milroy Lecturer for 1906.

The following communications were received: 1. From the secretary of Queen Victoria's Jubilee Institute for Nurses asking the College to nominate a representative for a term of three years from the end of February next in place of Sir Dyce Duckworth who retires by rotation but is eligible for re-election. Sir Dyce Duckworth was unanimously re-elected. 2. From the secretary of the Royal

College of Surgeons of England reporting certain proceedings of their Council. 3. From Colonel C. W. Long, M.P. (chairman of an association formed in 1903), moving the College to memorialise the Government to give effect to recommendation 50 of the Inter-Departmental Committee on Physical Deterioration by appointing a commission of inquiry into the prevalence and effects of syphilis on the national health. The matter was referred to the Council of the College for consideration and report.

The following Fellows were elected to serve on the Council: Dr. Thomas Buzzard, Dr. J. Watt Black, Dr. T. Clifford Allbutt, Dr. W. Hale White, and Dr. R. Percy Smith.

Dr. F. de Havilland Hall was elected a member of the finance committee until July, 1906, in place of Sir Isambard Owen who has resigned.

The PRESIDENT drew attention to a fine portrait of Harvey which had been offered to the College and it was resolved to purchase it and to add it to the collection of portraits already in the possession of the College.

The quarterly report of the College finance committee, dated Jan. 12th, was received and adopted.

A report was received from the committee of management dated Dec. 5th, 1904, recommending that the Liverpool Stanley Hospital should be added to the list of general hospitals recognised by the Examining Board of England, and that the Municipal College, Grimsby, should be added to the list of institutions recognised by the Examining Board in England for instruction in chemistry, physics, and practical chemistry. The report was adopted.

A report from the laboratories committee dated Dec. 2nd, 1904, was received and adopted.

A list of books and other publications presented to the library during the past quarter was received and the thanks of the College were ordered to be returned to the donors.

The PRESIDENT then dissolved the Comitia.

MEDICINE AND THE LAW.

The Name "Benedictine."

A MOTION was heard by Mr. Justice Buckley recently for an injunction forbidding a Welsh company from applying the name "Benedictine" to a liqueur of their manufacture. The party complaining was the Société Anonyme de la Distillerie de la Liqueur Bénédictine de l'Abbaye Fécamp, and the evidence on its behalf was to the effect that the word "Benedictine" was generally understood in the wine trade to mean their liqueur and no other. This is so much the case that it is a little surprising to find the learned judge dismissing the application as "ridiculous," a somewhat strong term to apply when a business firm finds its well-known product imitated and the imitation sold under the name which the original firm has made famous. The evidence, however, showed that the liqueur of the defendants although sold in bottles which themselves to some extent were imitations, was accompanied by labels and advertised by circulars which with complete candour proclaimed that it was made in Great Britain, and which boasted that the secret of the Abbaye Fécamp had been discovered by the British firm who used identical materials. This, of course, is not a representation that the new liqueur is made abroad by the foreigner. No evidence was given as to the actual composition of the two liqueurs and Mr. Justice Buckley's decision was simply on the question of the name. It proceeded on the assumption that the claims of resemblance between the two liqueurs were justified in fact. No doubt, it would not be held that a man had the right to sell an altogether inferior article and a mere imitation by boasting that it was precisely similar to another of recognised merit. To do this would be to damage the reputation of the latter by means of a misrepresentation.

Arsenic on Easy Terms.

Arsenic has figured as the instrument of death in so many famous crimes and has so often been detected in these only through a repetition of its use or some chance circumstance that it is safe to conclude that in other instances human life has been taken by its means without the murder being brought home to the assassin. That it may be taken accidentally must also be remembered in considering a prosecution by the Pharmaceutical Society which led to the conviction and fining of William Andrews, a ratcatcher, at Stratford on Jan. 27th. An inspector of the Pharmaceutical Society had written to the defendant inclosing a postal order for 3*s.* 6*d.* and asking for "Hammond's Remedy for Rat Killing." In return he received a cake, apparently of meal, which upon analysis was found to weigh four ounces and to contain one and a half ounces of arsenic. The bench declined to accept the excuse that the defendant was ignorant of the law—a defence which the common law of England does not recognise—and fined him £2 with 4*s.* costs. Regulations for the sale of patent medicines such as those referred to in THE LANCET of Jan. 28th, p. 241, as having been introduced in New Zealand would presumably include such articles as "Hammond's Remedy for Rat Killing" and would assist in the suppression of a dangerous traffic the disappearance of which none would regret, even if it involved pecuniary loss to ratcatchers.

COCOA CHEMICALLY AND PHYSIOLOGICALLY CONSIDERED.

II.[1]

IN the previous article it was shown that there are practically two classes of cocoa in the English market—one which after fermentation is simply roasted, ground, and the fat expressed and another in which in addition to the above the natural salts are increased. The cocoas of the former class commonly exhibit an acid reaction and those of the latter class either a neutral reaction or a slightly alkaline one due not to free alkali but to the presence of alkaline salts. As these different methods of manufacture are calculated to modify the properties and the composition of the cocoa which may affect its value as a food and a beverage it is interesting to determine how far this is so. We therefore instituted a series of experiments directed to ascertain, first, the *real* solubility of the cocoas in boiling water and the amount and the nature of the soluble constituents; secondly, the *apparent* solubility of the cocoas judged from the amount of material subsiding from the infusion; thirdly, the digestibility of the two classes of cocoa in artificial gastric and pancreatic juice; and fourthly, the action of acids and alkali in the absence of ferment.

For the purpose of these experiments Cadbury's cocoa was taken as a type of one method of manufacture and Van Houten's cocoa as a type of the other, while Plasmon cocoa was included in the investigation as representing a cocoa containing added matter (plasmon or dried milk proteid).

In determining the real solubility of the cocoa in boiling water the directions contained upon the respective labels were strictly followed in making the infusion. The results below relate to the total dissolved matters, the mineral matter, organic matters, and proteid dissolved. The amount of proteid dissolved was arrived at by determining the amount of nitrogen in the undissolved residue and deducting this from the total amount of nitrogen present as proteid in the cocoa.

Cocoa.	Total dissolved matters. Per cent.	Mineral matters. Per cent.	Organic matters. Per cent.	Proteid. Per cent.
Cadbury's ...	19·80 ...	3·20 ...	16·60 ...	5 90
Van Houten's...	23·00 ...	5·20 ...	17·80 ...	10·55
Plasmon cocoa	50 40 ...	5·00 ...	45·40 ...	38 21

Plasmon cocoa consists approximately of 60 parts of plasmon and 40 parts of cocoa, the latter belonging to the class of cocoas which are either neutral or slightly alkaline in reaction. The high percentage of soluble matters and of soluble proteid, therefore, in this cocoa is due to added proteid. The solubility of the proteids of cocoa is evidently influenced by the method of manufacture, as we should expect. Thus it is very decidedly increased in Van Houten's cocoa in which the natural alkaline salts are increased, while Cadbury's cocoa showing an acid reaction yields distinctly less proteid to hot water. It should be remarked, however, that the real solubility of cocoa must depend also upon the degree to which the cocoa is reduced to powder. Van Houten's cocoa is exceedingly finely ground, in fact comminuted, and this must be an obvious factor in the case, for according to the fineness of the powder so will be the proportion of the nitrogenous and other principles freed from their environment. Van Houten's cocoa is practically an impalpable powder and the most finely ground that we have examined. While it yields about the same amount of organic matters to hot water as does Cadbury's yet the proportion of proteid dissolved is nearly twice as much. Summing up, Plasmon cocoa yields to boiling water 70 per cent. of its proteid, Van Houten's 60 per cent., and Cadbury's 33 per cent., the total proteid of the cocoas respectively being 54·43 per cent., 17·25 per cent., and 18·60 per cent.

---

[1] No. I. was published in THE LANCET of Jan. 7th, 1905, p. 47.

By the *apparent* solubility of cocoa is meant the quantity of the cocoa which remains suspended in the infusion after a certain time. This will depend again upon the fineness of the powder, while obviously as the percentage of natural salts is increased the amount of matters kept in suspension will be greater. This is a matter of considerable importance not only from a dietetic point of view but from an economical one also. It follows that the use of cocoa which yields the greatest amount of sediment in a short time in the cup is very liable to be attended with waste, for sediment is as a rule rejected and it must contain some of the important food principles of the cocoa. Such waste, however, could, of course, be obviated by occasionally stirring the infusion or by thickening it with milk or even starch. It is clearly an advantage, however, when a cocoa yields a minimum amount of sediment in a reasonable time. The word "soluble" is used in this sense by manufacturers of cocoa.

One gramme of each cocoa was heated with boiling water and made up to 100 cubic centimetres in a graduated cylinder. The volume of sediment was read off after half an hour with the following results :—

Cadbury's	5·0	cubic centimetres.
Van Houten's... ...	1·0	,, ,,
Plasmon cocoa ...	3·0	,, ,,

It appears from these results that the *apparent* solubility of various cocoas differs widely. Thus Cadbury's cocoa and plasmon cocoa yield an abundance of sediment when treated with boiling water and allowed to stand, while Van Houten's cocoa yields very little sediment even after standing for some hours. In practice, a cup of cocoa would not be standing more than half an hour when intended for consumption. The actual proportion of cocoa consumed, however, is clearly dependent upon its degree of apparent solubility, the extent, in fact, to which the cocoa remains suspended. The presence of natural salts increases the apparent solubility, which is further enhanced when the fineness of the powder is extreme. There is thus an important economy in the use of a cocoa which gives a negligible quantity of sediment in the cup just as there would be in the use of a beef-tea which contained albuminous particles in such a fine state of division as to result in practically no sedimentation. The order of sedimentation beginning with the cocoa which gives the least is as follows: Van Houten, Plasmon, Cadbury. It is interesting to observe that Plasmon cocoa yields a comparatively large sediment, and further, this sediment contains a considerable proportion of plasmon or milk proteid. Since plasmon is regarded as a soluble form of milk proteid it would appear that when combined with cocoa, at any rate, its solubility is interfered with.

The next experiments relate to the behaviour of cocoa under the action of artificial gastric and pancreatic juice. The results are calculated to give some idea of the fate of cocoa in the body, though necessarily the action taking place *in vivo* would be more complete than that taking place *in vitro*. Nevertheless the experiments being carried out under precisely the same conditions the results may be said to have a comparative value. The activity of the ferments was first ascertained and, as a matter of fact, Benger's liquor pepticus and liquor pancreaticus were found to be most trustworthy for the purpose. The cocoa infusion in each instance was prepared in the manner directed by the [illegible] water and the infusion then [illegible] the body (100° F.). A [illegible] s added and the whole mixture was kept for four hours at a constant temperature and occasionally stirred. In the case of gastric digestion the mixture was acidified with hydrochloric acid until of the acid strength of the gastric juice and in the pancreatic digestion the fluid was made alkaline with carbonate of sodium. The following figures show the percentage amount of the total proteid hydrolysed by the gastric and pancreatic ferments respectively after four hours :—

	Gastric digestion.	Pancreatic digestion.	Undigested proteid.
Cadbury's... ...	40·45	31·40	28·15
Van Houten's ...	67·20	4·11	28·69
Plasmon cocoa...	37·50	56·20	6·30

The results are of particular interest in that they show that the two methods adopted in the preparation of cocoa determine the relative digestibility of the cocoa in one or other of the digestive juices. Thus Van Houten's cocoa proves to be readily digestible in the gastric juice, the bulk of the proteid yielding to that digestive agent. While Van Houten's cocoa readily yields 67·20 per cent. of its proteid to the hydrolysing action of gastric juice, Cadbury's similarly yields 40·45 per cent. On the other hand, in the pancreatic juice Cadbury's yields 31·40 per cent. more of its proteid and Van Houten's 4·11 per cent. In other words, the latter cocoa is much more quickly digestible than the former, although both are ultimately digested to about the same extent after the united action of artificial gastric and pancreatic juices so far as regards their proteid constituents. It should be pointed out that in these experiments *in vitro* the infusion was constantly stirred but in practice, as has been already mentioned, the amount of cocoa actually reaching the gastric and pancreatic juices in the body is not represented by the spoonful of cocoa placed in the cup. According to the kind of cocoa used a more or less varying proportion of cocoa is left as a sediment in the cup. To make, therefore, a really practical comparison the infusion in the cup should after a time be poured off the sediment and then be submitted to the action of the artificial digestive juices. The cocoas giving the least sediment would obviously give the most favourable result. The more finely divided, too, the particles of cocoa the more amenable is it likely to be to the action of digestive fluids, the proteids *inter alia* being unlocked, so to speak, by the process. The proportion of proteid digested as shown in the above table is based upon the following amounts originally present in the cocoas:—Cadbury, 18·60 per cent.; Van Houten, 17·25 per cent.; and Plasmon cocoa, 54·43 per cent. In the literature on this subject we find that the amount of proteid given by other observers is generally in excess of the truth, for the reason probably that the amount of proteid has been based on the total quantity of nitrogen found. Since, however, cocoa contains on an average 1·5 per cent. of theobromine (equal to 0·5 N) its equivalent of nitrogen should be deducted before calculating the proteid.

It has already been pointed out in regard to Plasmon cocoa that, in spite of statements as to the solubility of plasmon itself, the cocoa yields a relatively large sediment containing plasmon. This suggests that some constituent, possibly cocoa-red or tannin, interferes with the solubility of the proteid. However that may be, the same restraining effect appears in evidence in the experiments with artificial gastric juice, for, in spite of the very [illegible] present in Plasmon cocoa, only [illegible] in gastric juice, as against 40 [illegible] cocoa and 67·20 per cent. in Van Houten's cocoa. The conclusion is suggested that, at any rate in gastric digestion, the natural proteids of cocoa resolve more easily than does dried milk proteid. Whatever restraining effect the constituents of cocoa may possess on the gastric solubility of dried milk proteid it is evident from these experiments that it is readily digested in artificial pancreatic (alkaline) juice, no less than 93·70 per cent. being hydrolysed.

The residue of cocoa after four hours' peptic and pancreatic digestion respectively was dried and weighed, the result giving, so far as experiments *in vitro* go, the total undigested matter. It should be stated that this undigested matter practically contains all the original fat of the cocoa since the power of artificial pancreatic juice actually to digest fat is very feeble, though to some extent it is probably capable of hydrolysing it. In the following results, therefore, the fat is deducted.

Undigested Residue after the Digestion of Cocoa in Artificial Peptic and Pancreatic Juices.

	Undigested.	Digested (by difference).
Cadbury's	31·73	68·27
Van Houten's...	31·65	68·35
Plasmon cocoa	14·88	85·12

The above results are the mean of six distinct experiments. Even with digestion experiments "in the test-tube" it is abundantly evident that cocoa contains a very considerable amount of true food material. The proportion of undigested residue in Plasmon cocoa is of course much less than in the pure cocoas but then this is due to the large excess of proteid. In the one case we have the cocoa digested; in the other chiefly the plasmon. Plasmon unmixed with cocoa is undoubtedly digestible; its digestibility, however, in the gastric juice is considerably diminished by the presence of cocoa, owing probably to the effect of cocoa-red or tannin. On the other hand, the digestibility of the natural proteid constituents of cocoa is apparently not affected. In view, therefore, of the fact that cocoa contains true food material in approximately physiological proportions in relation to the amounts of proteid, fat, and carbohydrate, the addition to it of foreign proteid must be regarded as physiologically superfluous. It amounts to an excessive proportion of nitrogenous food at the expense of fat and carbohydrates. Physiologically speaking, the dilution of cocoa with a carbohydrate such as starch or sugar would be a more rational proceeding, since as the experiments show cocoa contains a valuable proportion of digestible proteid as well as fat, starch, and other carbohydrates.

It has been said that "without proteid we die," and it would be equally true to assert that with nothing else but proteid in the diet we should die also, since the other elements, fat, carbohydrates, and mineral matter, are equally essential. When these elements are not present in physiological proportions the food is not complete, it is ill-balanced and not in accordance with the requirements of the body. The word nitrogenous is not synonymous with the word nutritive. Cocoa, as will be seen from a reference to the average analyses given in the previous article, approaches in composition to a complete food such as milk, but, unlike milk, it is necessarily not capable of being consumed in large quantities. Its mildly stimulating properties must further be taken into account in connexion with its use as an article of everyday diet and as an admitted restorative.

Lastly, it is interesting to note the behaviour of cocoa under the action of weak acids and alkalies in the absence of organic hydrolytic agents (ferments) altogether. Practically 93 per cent. of cocoa is soluble either in weak acid or alkali, some 7 per cent. of indigestible fibre remaining, as the following results show:—

Cocoa.		Soluble in weak acids.		Soluble in alkali.		Insoluble in both.		Total soluble.
		Per cent.		Per cent.		Per cent.		Per cent.
Cadbury's	...	41·50[1]	...	51·70	...	6·80	...	93·20
Van Houten's		41·10[2]	...	51·70	...	7·20	...	92·80
Plasmon	...	58·10[3]	...	39·60	...	2·30	...	97·70

These results would appear to indicate that probably a larger proportion of cocoa would be utilised in the metabolic processes of the human body than is shown in experiments conducted *in vitro* with artificial digestive juices.

Public Health and Poor Law.

LOCAL GOVERNMENT BOARD.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

On Small-pox in the Dewsbury Union, by Dr. S. W. WHEATON.[4]—Dr. Wheaton gives in this report a vivid picture of the local neglect and maladministration which have been so largely responsible for the heavy epidemic of small-pox which attacked Dewsbury and adjoining towns during the past autumn and is even yet not entirely at an end. The whole of the Dewsbury union, which comprises Dewsbury itself, three other municipal boroughs—Batley, Morley, and Ossett—and also ten smaller districts, has long been known for its hostility to the administration of the vaccination law. This was particularly marked in years previous to 1891–92, when Dewsbury and its neighbourhood suffered from a severe epidemic of small-pox which was the subject of an elaborate analytical study made by Dr. Sidney Coupland on behalf of the Vaccination Commission. Dr. Coupland's observations formed a convincing demonstration of the protective effect of vaccination which was manifested during that epidemic, but it is evident that they have had little effect on the Dewsbury guardians who have continued to do as little as possible to carry out their vaccination duties. As a result, at the beginning of last year's epidemic the proportion of unvaccinated children was extremely high. The adults also no doubt comprised a large proportion of unvaccinated, although it is probable that the proportion of comparatively well-protected persons among them was larger than in many towns owing to the extensive revaccinations in 1891–92 and to the number of persons who were attacked by small-pox in those years. It is usually claimed by antivaccinationists in support of their position that an epidemic of small-pox can be averted by "modern methods"—i.e., isolation, disinfection, and observation of "contacts"—and experience shows that where these methods are stringently applied (together with prompt vaccination of those known to be exposed to infection) a town with a bad record for infantile vaccination may nevertheless often keep an invasion of small-pox within relatively small limits. In the neighbourhood of Dewsbury, however, the local authorities failed to realise the need for providing adequate means of isolation and disinfection which unfortunately have to be faced by every large district so long as our vaccination laws relate only to infants and are specially called for in places where infantile vaccination is habitually neglected. It is not surprising, therefore, that the outbreak from which the neighbourhood has suffered has been severe. Dr. Wheaton's report relates to visits to the localities concerned during the earlier stages of the epidemic. By the middle of October last there had occurred in 1904 412 cases of small-pox in Dewsbury, 84 in Thornhill, 118 in Ravensthorpe, and many more in Ossett and other districts in the union. Dr. Wheaton found that the vaccination authority, the Dewsbury guardians, was doing practically nothing, although timely provision of assistance to the public vaccinators would have been invaluable, while the arrangements of the several sanitary authorities to deal with small-pox were most inadequate and unsatisfactory. In Dewsbury the small-pox hospital (situated at the cemetery) was "a collection of small galvanised iron buildings and had a very dilapidated and forbidding appearance; nearly all the windows were broken, the apertures having been stuffed with paper or rags. ...... A fœtid smell was noticeable outside the hospital and heaps of refuse and partially consumed food lay around it. ...... On entering the building the fœtor was extreme; the wards were much overcrowded and were pervaded by flies, which arose in swarms from the patients when disturbed. The interiors of the wards were very dirty.' In charge of 76 patients (in many of whom the disease was of a severe type) were only eight nurses who were provided with wholly inadequate quarters. Extension of small-pox from the hospital to dwellings in its neighbourhood, whether due to communications between patients and their friends outside, to general maladministration, to atmospheric convection, or to all three causes together, was apparently taking place. Dr. Wheaton ascertained that the residents of houses within a quarter of a mile of the site were being attacked by small-pox in exceptional numbers. The Thornhill temporary small-pox hospital, though clean, was also inadequate and overcrowded. On the female side "17 persons were sleeping in 14 beds in a ward intended for six only." The Ravensthorpe district had an arrangement to send patients to the Dewsbury hospital but this could not be continued owing to the demands of Dewsbury itself. Consequently in this district cases of small-pox were left at their homes without proper nursing and often under conditions which involved the sick and the healthy occupying the same sleeping room or the same bed. Graphic instances of this objectionable state of things are given in the report and Dr. Wheaton observes that it would hardly be credited that such conditions were capable of existence in a civilised country. In other districts visited the position, though not as bad as at Ravensthorpe, was sufficiently serious. Dr. Wheaton records the advice which he gave to each of the authorities concerned and which fortunately was in many cases followed with satisfactory results. Although a large number of people in the Dewsbury union, particularly the "contacts" in invaded houses, were persuaded by fear of small-pox to protect themselves and their families by vaccination, this was often not the case. Some of the Ravensthorpe people appeared "to have become accustomed to the presence of small-pox, regarding it as a calamity which it was hopeless to fight against." In one instance, when small-pox was going through the household, "I urged the father to have this remaining unvaccinated child vaccinated, but he declined. I *asked him if he was not convinced of the* protection afforded by vaccination since he knew that the medical men who were constantly going in and out of the infected houses had none of them taken the disease, but he replied that medical men were protected by a charm with which they would not part." As our readers are aware,[5] the inactivity of the guardians who refused to open vaccination stations led to special action by the Local Government Board which made the new departure of issuing an Order under Sections 130 and 134 of the Public Health Act, 1875, to the Dewsbury, Ravensthorpe, and Soothill districts empowering the medical officers of health to vaccinate or to revaccinate any person in immediate [illegible] visitors if the medical officer of health so advised. Later returns will no doubt [illegible] success of these and o[illegible] which we understand [illegible] Dr. Wheaton reports. The epidemic of small-pox in this union must have entailed a severe strain not only on officers of the central and local public health authorities but also upon many of the medical practitioners in the districts concerned.

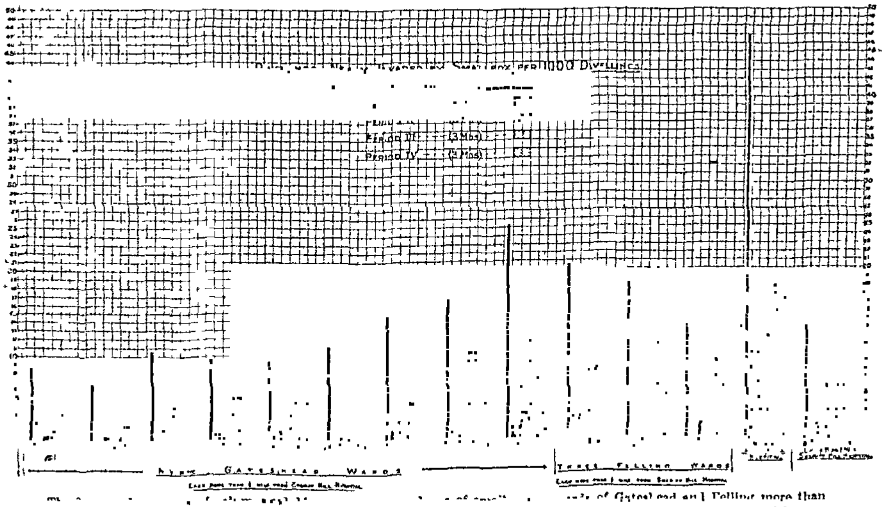
On Small-pox in Gateshead and Felling, 1903-04, in relation to Sheriff Hill Hospital, by Dr. G. S. BUCHANAN.[6]—This report relates to prevalence of small pox in very different circumstances to those of Dewsbury. The districts [illegible] accommodation and then, and all through the epidemic which followed during the next 13 months, notified cases were removed to hospital almost invariably within 12 hours, and usually within a much shorter time, from the receipt of notification. Disinfection of dwellings, bedding, clothing, and the like was practised systematically. "Contacts" in Gateshead were kept under regular observation and in Felling were maintained at their homes at the expense of the district council. Both districts are comprised in the Gateshead union, in which infantile vaccination appears to be enforced fa[illegible]ed by the Gateshead [illegible]ed the protection of [illegible] Usually, *though by* [illegible]pted vaccination or revaccination and a large majority of them did not contract small-pox. Notwithstanding the various precautions adopted the epidemic reached considerable dimensions. From April, 1903, to May, 1904, Gateshead, with a population of 109,000, had 316 houses invaded and 510 cases of small-pox; Felling with a population of 22,500 had 106 houses invaded and 155 cases. The latter district is in the administrative county of Durham and in March, 1904, the county medical officer of health, Dr. T. Eustace Hill, drew attention to the exceptional incidence of the disease on the portions of Felling nearest to the Sheriff Hill Hospital in which all the cases of small-pox which arose in Gateshead were being treated. This hospital, *though situated within the borough of Gateshead, is close* to the Felling boundary. Dr. Hill and Dr. W. E. Peacock, medical officer of health of Felling, concluded that the exceptional incidence was to be ascribed to aerial convection of infection from the hospital. The subject of the distribution of small-pox in different areas of Gateshead and Felling was then investigated by Dr. Buchanan on behalf of the Local Government Board. His report is illustrated by maps and diagrams and forms an interesting contribution to the subject of the influence of a small-pox hospital on the neighbourhood. The facts recorded by Dr. Buchanan make it quite certain that small pox was exceptionally severe in parts of Gateshead and Felling which are near the hospital. Within half a mile of it there are 1297 dwellings and the proportion of these invaded by small-pox was 47 per 1000 as against 14 per 1000 in the rest of Gateshead and Felling more than half a mile from the hospital. Within a quarter of a mile of the hospital there are 330 dwellings; 27 of these, or 82 per 1000, were invaded. It might be supposed that these figures could be accounted for by the accidental occurrence of undetected cases in some house or houses near the hospital but this suggestion is disposed of by the study of



of Gateshead and Felling more than

the facts given for different periods of the epidemic which show that all through the 13 months the same disproportionate incidence was observed. Dr. Buchanan has also applied a very searching test by comparing the intensity of small-pox prevalence within the half-mile area with that in 12 wards of Gateshead and Felling each of which is more than half a mile from the hospital and contains somewhat about the same number of dwellings as the half-mile area. He finds that the incidence on the half-mile area exceeded that in any one of these wards and that this is shown not only when the epidemic is taken as a whole but also when it is divided into three-monthly periods. We reproduce here the diagram in the report which illustrates this. Dr. Buchanan also gives reasons for believing that the influence of the hospital was exerted on certain localities near, but more than half a mile from, Sheriff Hill Hospital. His conclusions *on the facts obtained are that there is no evidence* that maladministration or absence of proper precautions in connexion with the traffic to and from the hospital was responsible for the exceptional and sustained incidence on the half-mile area and that the probable explanation is that here, as in other well-known cases, aerial transmission of infection has occurred. Dr. Buchanan agrees also with the observations of Dr. Hill that the direction of prevalent gentle winds at Sheriff Hill accords with this explanation. It is in any case evident that the use of this hospital has been responsible directly or indirectly for a material portion of the epidemic which has occurred during 1903–04 in these two administrative districts and Dr. Buchanan concludes by stating that he has no hesitation in recommending that it should no longer be used for the isolation of small-pox.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8914 births and 5520 deaths were registered during the week ending Jan. 28th. The annual rate of mortality in these towns, which had been 19·9, 17·5, and 18·1 per 1000 in the three preceding weeks, further rose to 18·4 per 1000 last week. In London the death-rate was 18·9 per 1000, while it averaged 18·1 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 9·0 in Walthamstow, 9·3 in Handsworth (Staffs), 10·5 in Hornsey, 12·0 in King's Norton, 12·3 in Southampton, 13·2 in Willesden, and 13·7 in Leyton and Portsmouth; the highest rates were 23·3 in Bootle, 24·1 in West Hartlepool, 24·2 in Nottingham, 24·9 in Stockton-on-Tees, 25·4 in Rochdale, 27·1 in Rhondda, 28·9 in Merthyr Tydfil, and 29·7 in Middlesbrough. The 5520 deaths in these towns included 376 which were referred to the principal infectious diseases, against 399, 378, and 358 in the three preceding weeks; of these 376 deaths, 124 resulted from measles, 107 from whooping-cough, 61 from diphtheria, 37 from diarrhœa, 28 from scarlet fever, 15 from "fever" (principally enteric), and four from small-pox. In Croydon, Hornsey, Brighton, Southampton, Rochdale, York, and seven other smaller towns no death from any of the principal infectious diseases was registered, while they caused the highest death-rates in East Ham, Leyton, Plymouth, Grimsby, Nottingham, Bootle, Stockton-on-Tees, Sunderland, and Merthyr Tydfil. The greatest proportional mortality from measles occurred in East Ham, Leyton, Bristol, Nottingham, Burnley, Stockton-on-Tees, South Shields, and Merthyr Tydfil; from diphtheria in Grimbsby and Bootle; from whooping-cough in Hastings, Hanley, Aston Manor, Grimsby, Preston, Barrow-in-Furness, Hull, and Sunderland; from "fever" in Bootle; and from diarrhœa in Ipswich and Plymouth. Of the four fatal cases of small-pox registered in the 76 towns last week one belonged to London, one to Leeds, one to Gateshead, and one to Newcastle-on-Tyne. The Metropolitan Asylums Hospitals contained 15 small-pox patients at the end of last week, against 18, 19, and 18 at the end of the three preceding weeks; no new case was admitted during the week, against one in each of the three preceding weeks. The number of scarlet fever cases remaining under treatment in these hospitals and in the London Fever Hospital, which had been 2309, 2192, and 2174 on the three preceding Saturdays, had further declined to 2096 on Saturday, Jan. 28th; 251 new cases were admitted during the week, against 187, 194, and 225 in the three preceding weeks. The deaths in London referred to pneumonia and diseases of the respiratory system, which had been 443, 301, and 377 in the three preceding weeks, further rose last week to 478 and were 47 above the number in the corresponding period of last year. The causes of 72, or 1·3 per cent., of the deaths in the 76 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Leicester, Leeds, Newcastle-on-Tyne, Cardiff, and 46 other smaller towns; while the largest proportions of uncertified deaths were registered in Portsmouth, Birmingham, Aston Manor, Liverpool, St. Helens, Rochdale, Sheffield, and Gateshead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 20·6, 21·6, and 20·1 per 1000 in the three preceding weeks, rose again to 20·3 per 1000 during the week ending Jan. 28th and was 1·9 per 1000 above the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 15·8 in Paisley and 16·5 in Dundee to 23·8 in Greenock and 26·5 in Aberdeen. The 681 deaths in these towns included 44 which were referred to whooping cough, nine to diphtheria, nine to diarrhœa, six to measles, six to "fever," and five to scarlet fever. In all, 79 deaths resulted from these principal infectious diseases last week, against 79, 85, and 72 in the three preceding weeks. These 79 deaths were equal to an annual rate of 2·4 per 1000, which was 1·3 per 1000 above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of whooping-cough, which had been 37, 45, and 33 in the three preceding weeks, rose again last week to 44, of which 25 occurred in Glasgow, seven in Greenock, three in Edinburgh, three in Aberdeen, three in Paisley, and three in Perth. The deaths from diphtheria, which had been four, five, and three in the three preceding weeks, increased to nine last week, and included four in Glasgow and three in Edinburgh. The fatal cases of diarrhœa, which had been 13, 16, and 17 in the three preceding weeks, declined again last week to nine, of which five were registered in Glasgow and three in Edinburgh. The deaths from measles, which had been 14, 12, and 15 in the three preceding weeks, decreased to six last week and included three in Aberdeen. The fatal cases of "fever," which had been eight, four, and three in the three preceding weeks, rose again last week to six and included two in Glasgow, two in Aberdeen, and two in Greenock. The deaths from scarlet fever, which had been three, three, and none in the three preceding weeks, rose last week to five, of which two occurred in Edinburgh and two in Aberdeen. The deaths referred to diseases of the respiratory organs in these towns, which had been 182, 183, and 156 in the three preceding weeks, rose again to 163 last week and were 35 in excess of the number in the corresponding period of last year. The causes of 25, or nearly 4 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 25·6, 22·6, and 21·2 per 1000 in the three preceding weeks, rose again to 25·5 per 1000 during the week ending Jan. 28th. During the past four weeks the death-rate has averaged 23·7 per 1000, the rates during the same period being 17·5 in London and 8·9 in Edinburgh. The 185 deaths of persons belonging to Dublin were 31 in excess of the number in the preceding week, and included 18 which were referred to the principal infectious diseases, against five, 21, and 10 in the three preceding weeks; of these 13 resulted from measles and two from scarlet fever, two from whooping cough, and one from diarrhæa, but not any from small-pox, from diphtheria, or from "fever." These 18 deaths were equal to an annual rate of 2·5 per 1000, the death-rates last week from the principal infectious diseases being 1·2 in London and 1·9 in Edinburgh. The fatal cases of measles, which had been three, 12, and five in the three preceding week, rose again last week to 13. The two deaths from scarlet fever corresponded with the number in the preceding week. The 185 deaths in Dublin last week included 26 of children under one year of age and 54 of persons aged 60 years and upwards; the deaths both of infants and of elderly persons were in excess of the respective numbers recorded in the preceding week. Four inquest cases and four deaths from violence were registered; and 70, or nearly two-fifths, of the deaths occurred in public institutions. The causes of eight or more than 4 per cent. of the deaths registered in Dublin last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet Surgeons: R. Hardie to the *Vivid* for the *Commonwealth*, and on recommissioning; R. A. Fitch and J. A. Thompson to the *Drake*. Staff Surgeons: W. R. Trythall to the *Diamond* on commissioning; E. S. Miller to the *Vivid*; and R. T. Gilmour to the *Egmont*. Surgeons: H. C. Whiteside to Malta Hospital; A. R. Schofield to the *Vivid* for disposal; E. D. J. O'Malley to the *Pembroke* for Chatham Dockyard; A. F. Fleming to the *Lapwing*; E. R. L. Thomas to the *Sphinx*; A. D. C. Cummins to the *Empress of India*; and W. N. Horsfall to the *Exmouth*.

ARMY MEDICAL SERVICE.

Surgeon-General W. J. Fawcett, C.B., Army Medical Staff, to be Deputy Director-General, vice Surgeon-General A. Keogh, C.B., appointed Director-General (dated Jan. 20th, 1905).

ROYAL ARMY MEDICAL CORPS.

The following officers, on arrival in India, will be posted as follows: Major A. Kennedy to the 6th Division; Captain W. E. Hudleston to the Nagpur District; Captain J. G. Berne to the 6th Division; Lieutenant A. A. Meaden to the 5th Division. Major T. B. Beach, now in Bengal, is appointed to the Thames District for duty. Major C. E. Pollock is held in readiness for service in Malta, embarking about March 25th. Lieutenant-Colonel S. F. Freyer, C.M.G., on promotion, is transferred from the Home District to Aldershot for duty at the Cambridge Hospital.

Colonel W. Allan May, C.B., is appointed Principal Medical Officer for Salisbury Plain District.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Major S. Linton, having resigned his commission in the Volunteers, ceases to belong to the Army Medical Reserve of Officers (dated Jan. 28th, 1905).

INDIAN MEDICAL SERVICE.

The following gentlemen were successful at the examination for admission to the Indian Medical Service held on Jan. 24th and four following days:—

	Marks.		Marks.
Hamilton, A. F.	3572	MacWatters, M. R. C ..	3143
White, A. D.	3279	O'Neill, J. S.	3140
White, R. K....	3223	Boalth, W. H....	3215
Keaney, M. F.	3180	Hamilton, W. H.	3118
Wilson, N. M.	3166	Coppinger, C J.	3026
Buckley, H. C.	3150	Cunningham, J.	3024
Soltau, G. A.	3149	Falk, H.	3016

35 candidates (17 of whom had university degrees) competed for the 14 vacancies.

THE WAR IN THE FAR EAST.

Russia is at present the arena of revolutionary activity and as we have already said the events taking place there have had the effect of rivetting public attention on the [illegible] and of almost altogether [illegible] from the theatre of war in [illegible] political unrest in Russia must have been intensified by the news of the failure of [illegible]

[illegible] may be for the real interest of Russia to make peace and however much the Russian nation may wish it it is hardly [illegible] t present adopt [illegible] war now going [illegible] led except the facts that the hospitals are said to be filled with sick and wounded and that a bread famine exists to add to the miseries of the poorest classes of that city.

"Audi alteram partem."

RESEARCHES INTO THE ETIOLOGY OF CARCINOMA.

To the Editors of THE LANCET.

SIRS,—While thanking you for your appreciative annotation upon our paper which appeared in THE LANCET of Jan. 28th, p. 244, we feel obliged in the interests of cancer research to join issue with you in regard to your declaration that there is no analogy between the phenomena of finger-and-toe disease and those of carcinoma, which we are convinced can only have been made under a misapprehension as to the actual facts of the case. Had we thought that the point would be questioned we should certainly have dealt with it. It is one of several that we purposely did not touch upon, chiefly because the mere description of our observations necessitated a paper that we felt would already encroach too largely upon your valuable space.

The striking parallel that exists between the phenomena of finger-and-toe disease and those of carcinoma has been pointed out by several observers, but particularly by Dr. Gaylord, to whose papers we referred. Briefly, the phenomena of finger-and-toe disease (especially as observed in turnips) that are analogous to those of carcinoma are the following. The morbid changes consist essentially in a rapid, abnormal local proliferation of the cells of the plant, [illegible] tumour-like excrescences. [illegible] any period in the life of [illegible] be initiated and to proceed to the formation of a considerable local swelling in a previously healthy root which had completed its growth, which had been removed from the ground, and from which the leaves had been cut away. On section the localised tumours attached to the healthy portion have a general appearance which is comparable to that of an epithelioma of the lip. The morbid process very commonly goes on to ulceration, invasion of the tumour mass by putrefactive bacteria, and death of the host. The general health of the plant is always seriously affected from an early period of the disease. Inoculation of a healthy plant with material from an affected one does not result in the transmission of the disease. Tumours may, on the other hand, be grafted upon a normal plant and the subsequent tumour growth is formed exclusively by descendants of the grafted cells. The evidence goes to show that the morbid proliferation commonly begins at only a few points and that by multiplication of a small number of primarily infected cells tumour masses of large size may arise. Whilst the fact that the plasmodiophora brassicæ is the cause of the disease is beyond question, all attempts to cultivate the parasite [illegible] ling [illegible] ena [illegible] be considered to do so. Whilst the existence of this analogy is a striking and incontrovertible fact we would point out that it is not logically necessary for the support of the con[illegible] the ground of actual observa[illegible] carcinoma. We have not [illegible] brassicæ is the cause of carcinoma. We have merely maintained that a parasite of the same class is present in carcinomatous tumours. There are grounds for believing that there are several parasitic plasmodiophoræ, just as there are many parasitic bacteria, and it is extremely unlikely that the pathogenic action of each species is exactly the same.

We are, Sirs, yours faithfully,

W. FORD ROBERTSON,
HENRY WADE.

Laboratory of the Scottish Asylums, Edinburgh, Jan. 30th, 1905.

*** We are glad to know that Dr. Robertson and Mr. Wade recognise the importance of the omissions to which we drew attention. The letter which we print above implies that the writers have convinced themselves by personal observation and experiment that an analogy exists between the morbid changes of "finger-and-toe" disease in turnips and carcinoma in man. We have had no opportunity of investigating the nature of the evidence on which their opinions are based and we are therefore debarred from commenting upon it. It is otherwise with the published work of Gaylord, Woronin, Nawaschin, Behla, and Podwyssozki whom the writers have quoted. These investigators have not established either that cancer is an infective disease or that an analogy exists between the morbid processes of "finger-and-toe" disease and carcinoma any more than do the contributions of von Leyden and others to the same subject. If the writers have succeeded where earlier workers on the plasmodiophora have failed it is all the more necessary for them to supply a convincing demonstration of the fact. Until they do so they cannot claim to have done more than to have described and interpreted another cell inclusion in carcinoma and the serious criticisms of von Tubeuf, Lubarsch, and von Hansemann will still remain unanswered, as will the more general criticisms which have been passed upon the cell inclusions of cancer generally. We trust that workers with such a desire to be objective as Dr. Robertson and Mr. Wade will not only be able to solve the many contradictions in the literature on the relation of the plasmodiophora to cancer and cell inclusions generally but that they will succeed in establishing their thesis.—ED. L.

CERTIFICATES FOR MIDWIVES AND THE OBSTETRICAL SOCIETY OF LONDON.

To the Editors of THE LANCET.

SIRS,—In your issue of Jan. 28th there is a report of an inquiry held by the Central Midwives Board into a charge against a certified midwife of signing false certificates. As there is a passage in that report which is in danger of creating an impression contrary to fact and detrimental to the reputation of the Obstetrical Society of London, may I, as the witness whose evidence is concerned, be allowed a word or two by way of explanation? The statement that I made was to the effect that the Obstetrical Society of London some ten years ago was in the habit of occasionally accepting a certificate of attendance upon a smaller number of cases than the regulations required on the understanding that a supplementary certificate would be furnished before the day of examination showing that the candidate had by that time completed the required number. This is, of course, a very different thing from conniving at a false certificate, which is what your readers would naturally suppose from your report to be what the Obstetrical Society did.

I am, Sirs, yours faithfully,
A. HANNAM,
Secretary and Librarian of the Obstetrical Society of London.
Jan. 30th, 1905.

OVARIOTOMY IN A COTTAGE.

To the Editors of THE LANCET.

SIRS,—The unusually early age of the patient, who was only 11½ years old, impels me to report this case. I was called in to see the patient, a little girl, by Dr. R. McCandless of Rathfriland. She had a temperature of 101° F. and was suffering from colicky pains in the lower part of the abdomen with gastro-intestinal disturbance. These symptoms she had complained of more or less for the previous five months, but they had become much aggravated during the last few days with the elevation of the temperature. There was an obvious fulness of the hypogastrium and a tumour was plainly felt extending above the umbilicus, dull, fluctuating, very tense, and with clearly defined outlines. There was no dulness in the flanks and the tumour was unaltered on evacuating the bladder. There was a tuberculous family history and it was only this fact, coupled with the youth of the patient, who had shown no signs of early puberty, that cast any doubt upon the diagnosis of a frank ovarian cyst. I urged an immediate operation as the patient was in a serious condition but it was impossible to secure an experienced surgeon as her people were of very humble means and lived far away from any hospital, so that I had to undertake it myself. I did so with some diffidence, as neither the surroundings nor our equipment were ideal, but I had the advantage of valuable assistance from my friend Dr. J. A. D. Radcliffe and Dr. McCandless chloroformed the patient for us two days later. On opening the abdomen the tumour was found beneath the omentum with smooth surface, very tense, and filling the lower half of the abdominal cavity. On puncturing with trocar about one and a half pints of slightly blood-stained fluid escaped. The cyst was then found to spring from the left ovary, a few recent adhesions to the intestines being easily separated by the fingers. The appendages on the left side were removed along with the tumour. The right ovary appeared healthy and was left. On opening the tumour a mass of hair presented, revealing a dermoid cyst, and thus, I suppose, accounting for its development at so early an age. I would be glad to know, however, if such cases are at all common. The patient stood the operation well, although it was rather prolonged (one and a half hours), and made a good recovery. I removed the stitches ten days later and the wound was quite healed. The little girl is now running about and seems perfectly well.

I am, Sirs, yours faithfully,
J. HOPE REFORD, M.D. R.U.I.
Banbridge, co. Down, Jan. 26th, 1905.

SUNSHINE IN GUERNSEY.

To the Editors of THE LANCET.

SIRS,—It does not seem to be as widely known as it should be that this island is a highly favoured place as regards the large amount of sunshine it enjoys. A reference to the table given beneath will show that in 1904 Guernsey holds the record by 211 hours over Hastings, the sunniest town in England for that year:—

	Hours.		Hours.
Guernsey	1926	Cornwall	1660
Jersey	1866	Devonshire	1634
Hastings	1715	London	1328
Hurst Castle	1671	South of Ireland ...	1232

I am, Sirs, yours faithfully,
HY. DRAPER BISHOP,
Medical Officer of Health, States of Guernsey.
Jan. 28th, 1905.

ATMOSPHERIC CONDITIONS AND THE OCCURRENCE OF CEREBRAL HÆMORRHAGE.

To the Editors of THE LANCET.

SIRS,—I am much interested in Dr. J. W. Russell's contribution on the above subject in THE LANCET of Jan. 28th, p. 222, as since Dr. R. Hensleigh Walter and others so strongly suggested the influence of climatic conditions in deciding the onset of an attack of cerebral hæmorrhage I have been endeavouring to ascertain if any statistical proof could be obtained in favour of the belief which exists in the minds of many practitioners. The material at my disposal consists of a large number of death certificates and meteorological observations taken by myself. Only about 15 per cent. of death certificates give the duration of illness or date of attack I thought it might be interesting to see if deaths from apoplexy were more common under high or low pressure. Dealing first with the returns for Bath for three years—121 deaths—I found that 64 per cent. of the deaths took place when the atmospheric pressure was above the average of the three years, 29·84 inches, but the pressure was above the average on 57 per cent. of the days of these three years.

Dr. Russell takes the average pressure of 12 years as 29·376 inches; this, I suppose, is the uncorrected reading of the barometer, otherwise it seems low. He says that a larger number of cases occurred on days on which the barometric pressure was above the average than on those when a pressure below the average was recorded, the proportion in the total number of cases being almost exactly as 5 to 4 Singularly enough in the three years 1901–03, the days on which the pressure was above the average compared with days on which the pressure was below the average were almost exactly as 5 to 4. If the same ratio obtained during the 12 years 1891–1902, Dr. Russell's cases must have been fairly evenly distributed, but days of high pressure being more frequent than days of low pressure attacks of cerebral hæmorrhage are apparently more common on days of high pressure. Anyone wishing to confirm these figures can find meteorological records for London from 1882 onwards in Whitaker's Almanack.

The number of deaths from apoplexy in Bath being too few to afford statistics from which reliable conclusions could be drawn, I applied to Dr. D. S. Davies for permission to use the returns for Bristol and so obtained a total of 1575 certificates of deaths from cerebral hæmorrhage, apoplexy, or hemiplegia during the six years 1899-1904. The duration of illness or date of attack is only given in 299 of these certificates; these may not be representative as the date of attack may be more often stated when soon followed by death. In 70 per cent. of these cases death occurred within seven days and in80 per cent. within one month; 55 deaths, or 18 per cent., being within 24 hours of attack and for these rapidly fatal attacks the following table shows the corrected 9 A.M. readings of the barometer on the *day of death and also on the day preceding death; the* groups of cases would not be the same. I have also given an approximate estimate of the comparative frequency of attacks of cerebral hæmorrhage at each pressure when allowance is made for the proportion of days of such pressure.

	Barometric pressure (inches).			
	28·8 to 29·4	29 5 to 29 8	29·9 to 30·1	30·2 to 30·8
Death same day ...	6	15	17	17
Death next day ...	5	16	20	14
Estimated ratio ...	21	24	25	29

This empirical estimate founded on a small number of cases seems to support the argument which has been put forward, but a careful consideration of the monthly death-rates from cerebral hæmorrhage, which must be closely related to monthly attack-rates, in connexion with the meteorological conditions of each month for the past six years, leads me to the conclusion that atmospheric conditions have no special influence in determining an attack of cerebral hæmorrhage. January, February, and March are the months which show the highest death-rates from [illegible] lso from all other causes among [illegible] istrar-General's annual reports [illegible] from apoplexy and cerebral hæmorrhage varies always in the same direction as the death-rate of deaths from all causes among persons between 65 and 75 years of age, although these special diseases cause less than 10 per cent. of all deaths at such ages.

I am, Sirs, yours faithfully,
W. H. SYMONS.
Bath, Jan. 29th, 1905.

THE PRINCIPLES OF TREATMENT OF PNEUMONIA.

To the Editors of THE LANCET.

SIRS,—The able letter published in THE LANCET of Jan. 28th by Dr. A. G. Auld in criticism of my recent address on the Principles of Treatment of Pneumonia would have been still more welcome and valued had it been less exclusively *devoted to the discussion of debatable points of* theory. We are in full agreement in recognising that the first principle of treatment should be to prevent the invasion and the second to summon at once the force needed for [illegible] failed to [illegible] vived by [illegible] perhaps [illegible] ne point upon which we remain at variance. I still regard the risks which attach to lobar consolidation and to disablement of the lung as greatly in excess of any advantages which may belong to them in nature's scheme of cure. Preventive treatment, when it comes, will obviate pneumonic consolidation; and the anti-pneumococcus treatment of the future would presumably either forestall its occurrence or insure that arrest of its full development which it is the present endeavour to secure. Since an immediate cure cannot yet be attained, let us aim at as speedy a cure as may with safety be achieved with the remedies at our disposal. I believe that much can be effected by prompt and judicious action on the lines proved to be correct by the clinical results. Those measures which I have found to succeed in materially shortening or modifying the course of the attack are best described in one word by "elimination." To get rid of the germs and of the products of disease is to liberate the powers of health, which include any opsonic powers special to serum. How this is to be best effected and most quickly must have engaged the attention of many clinical workers. Their practical criticisms and suggestions would be most valuable as the special kind of help which the address was intended to invite.

I am, Sirs, yours faithfully,
WM. EWART.
Curzon-street, W., Jan. 28th, 1905.

PS.—*Dechloridation* does not at present form part of my treatment. As I have employed it in one case only, that reported in my address, I keep an open mind as to its merits with considerable doubt as to its value.

BED-GEAR FOR INVALIDS.

To the Editors of THE LANCET.

SIRS,—In a recent number you published the design of a useful invalid night-gown. There is another simple garment often wanted by invalids which it is generally difficult or impossible to procure at a short notice and which, it seems to me, might profitably be put upon the market by an enterprising firm. I refer to a bed-jacket or covering for the shoulders, arms, and chest. Most people when confined to bed, even for a short time, need such a covering and in many hospitals bed-jackets of various kinds are provided, but in private it is generally found necessary to improvise such a garment or to use shawls or similar articles, all of which are unsuitable, in one or other way, for the object needed. What is wanted is a fairly closely-fitting jacket, extending to the waist, easily opened front and back, and with *arms fastening at the wrists.* It could be made of any woollen or soft material, preferably, I think, knitted. Such a bed-jacket I find it almost impossible to get in private and I feel sure that if a garment of this sort were put upon the market it would find a very large demand and many households would provide themselves with two or three of different sizes for use in any case of illness. Only this week a patient of mine, a gentleman of a practical turn of mind, asked me why we medical men did not suggest a suitable bed-jacket for housewives to keep in readiness for sicl [illegible] arrangements of shawls, &c., all [illegible] fallen back on a dressing-gown w[illegible] lling the purpose of covering the arms and shoulders, still encumbered the bed with unnecessary skirts. I defended my profession as well as I could and said that we were not oblivious of such details as there had been quite lately in THE LANCET a beautiful picture of a convenient invalid nightdress. He insisted that his bed-jacket was of far greater importance and I am inclined to think he was right.

I am, Sirs, yours faithfully,
H. CAMERON KIDD.
Bromsgrove, Worcestershire, Jan. 27th, 1905.

INDIAN UNIVERSITY DEGREES AND THE ROYAL COLLEGE OF SURGEONS, OF ENGLAND.

To the Editors of THE LANCET.

SIRS,—In replying to a correspondent in your issue of Nov. 12th, 1904, you mention that "the L.M.&S. is not a degree—it is a diploma." The University of Bombay calls it "the degree of L.M. & S." There is no such degree as M.B. in this University. The Vice-Chancellor when admitting us as graduates of the University also pronounces at the convocation, "I admit you to the degree of L.M.&S." I admit that the University should not have used the word "Licentiate" while granting a degree and that the degree of M.B. should have been instituted when the Faculty of Medicine was founded.

In other universities, such as those of Madras, Dublin, &c., where licences are granted in addition to the degree of Bachelor of Medicine, the L.M.& S. may properly be regarded as a licence, but such is not the case with the University of Bombay. It would be well for the examining boards in the United Kingdom to read the calendars of the different universities before framing regulations concerning their mutual arrangements.

I am, Sirs, yours faithfully,
D. R. TATA, L.M. & S. Bombay.

*** If our correspondent will refer to p. 1448 of THE LANCET of Nov. 19th, 1904, he will there see a letter from Mr. S. B. Gadgil giving similar information and a note by ourselves stating that according to the testamur the L.M. & S. of the University of Bombay is called a degree.—ED. L.

THE TREATMENT OF STRABISMUS.

To the Editors of THE LANCET.

SIRS,—With respect to the operation of lengthening the tendon in cases of strabismus, described in THE LANCET of Jan. 28th (p. 254), by Dr. Landolt of Paris, I may perhaps be permitted to point out that I adopted a similar operation several years ago. In July, 1902, I read a note upon my method before the Ophthalmological Society and at the same time showed several patients upon whom the operation had been performed. I showed by diagrams that the tendon of the internal rectus might be lengthened in several ways without disturbing its insertion into the sclera. My communication was published in the Society's Transactions, vol. xxii. (1902), p. 276. I believe I am correct in claiming that I was the first to devise and to perform the operation now described by Dr. Landolt under the name of "muscular elongation." I am, Sirs, yours faithfully,

Welbeck street, W., Jan. 30th, 1905. SYDNEY STEPHENSON.

THE QUESTION OF TESTIMONIALS.

To the Editors of THE LANCET.

SIRS,—My attention has been called to an advertisement in THE LANCET with the *facsimile* of a letter, or part of a letter, commending a medical preparation, which is signed "Always truly yours, James Paget." It is not in the handwriting of Sir James Paget. The firm who sent it to you assure me that it has been in their possession for some 30 years and that they have always regarded it as genuine. It may, of course, be a copy of part of a private letter written long ago by Sir James Paget, but there is not the faintest reason for thinking that it was written to the firm who have lately used it as an advertisement.

I am, Sirs, yours faithfully,
Harley street, W., Feb 1st, 1905. STEPHEN PAGET.

THE TREATMENT OF PULMONARY TUBERCULOSIS.

To the Editors of THE LANCET.

SIRS,—I was glad to see Dr. A. C. Falkiner in THE LANCET of Jan. 14th draw attention to the harm done by "stuffing" in sanatorium treatment. A great many patients, and unfortunately some doctors, are dissatisfied unless they see a weekly gain in weight. But everyone who has any experience of sanatorium treatment must remember cases where increase of weight and progress of disease have occurred at the same time. But even in favourable cases a rapid increase of weight throws a great strain on the heart and produces breathlessness and this in spite of uphill walking. Quite recently I saw a young man return from a short stay at a sanatorium with his lung distinctly improved but a pulse-rate never below 125 and going up to 140 and over on exertion, which undoubtedly was due to a large deposit of fat, and yet he was taking walking exercise up to five and seven miles per day. Another evil effect of "stuffing" is the respiratory distress produced by distension of the stomach. In a well-known sanatorium I have seen patients rise from table and on walking a few yards commence gasping for breath. This is mainly produced by a large quantity of carbohydrate diet, which I maintain is the cause of much discomfort to phthisical patients. Of course the large amount of carbohydrate diet increases weight rapidly and so produces a favourable impression on the patient's friends of the result of the treatment. As to the effect of foggy, rainy winters on some cases, I think they do harm. I have watched cases even in Germany go downhill whenever the misty days began but improve on moving to a warmer and drier atmosphere. As in every department of medicine it is wrong to dogmatise, but I am quite sure that many cases, especially in females, have gone back through persevering in the "Spartan" methods during damp winters.

I am, Sirs, yours faithfully,
X.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Sanitary Condition of Simla.

THE occurrence of several cases of enteric fever in Simla in 1903 and 1904 amongst the European and Eurasian population has called attention to the sanitary condition of this station. I understand that the Lieutenant-Governor of the Punjab has appointed a committee, consisting of the sanitary commissioner, the judge advocate general, the sanitary engineer, and the civil surgeon, to make full inquiries into the various complaints which have of late been made. Amongst other grievances may be mentioned the trenching of night soil and the foul smells along the Mall and other roads, the collections of putrefying matter permitted to remain, and the shortage of water during the summer months. The drinking water is in quality undoubtedly good. Simla is growing and the station is overcrowded and complaint is made that the houses are too close together one above the other on the hillsides. The sewage works are not yet completed and the arrangements for carrying off the sewage water are insufficient. The septic tank at the bottom of the valley is admittedly a success but the incinerator used for burning refuse works slowly and is of a crude construction. The dhobies wash the clothes in hill streams but also doubtless in foul pools. The cows and buffaloes are kept in crowded and dirty byres in the villages. It is suggested that the annual occurrence of fevers amongst the natives every spring may be due to typhoid fever but the registration of the causes of deaths is so defective that the supposition is mere guesswork. The milk-supply is open to grave suspicion of constant contamination.

The Increasing Plague Mortality.

The plague mortality throughout India is rapidly mounting up. For the week ending Dec. 31st, 1904, there were 22,645 deaths, as compared with 19,465 for the previous seven days. The increase is almost entirely in the Punjab and the United Provinces. The detailed figures are: in the United Provinces, 9574, against 6822 last week; the Punjab, 4643, against 3940; Bombay districts, 3774, against 4154; Bengal, 2496, against 2005; Hyderabad State, 516, against 809; Madras districts, 367, against 353; Rajputana, 314, against 345; Mysore State, 282, against 319; and Central India, 121, against 132. I have frequently drawn attention to the absence of mention of Poona city in these weekly figures, notwithstanding that plague has been raging very severely for two or three months past. The deaths in this city have been included in the figures for the Bombay districts but it appears that the recent outbreak caused 71 deaths in September, 654 in October, and 1337 in November. Since the census of 1901, when Poona was credited with 153,320 inhabitants, there have been no less than 15,587 deaths from plague alone. The rate of mortality during November was 104 per 1000 per annum from plague. This city has lost nearly 40,000 of its inhabitants from plague since the first visitation of the disease in 1896.

Social Reforms amongst the Indian People.

The recent Indian Social Conference in Bombay indicates a great change in the opinions of the leaders of the various native communities upon questions concerning social reform. I find a resolution was passed that the custom of child marriage is most injurious to the physical, economic, and social well-being of the people. In the Baroda State marriage of girls under 12 years of age has been discouraged by recent legislation. A motion was also carried expressing cordial sympathy with the temperance movement and adopting the resolution passed at the last All India Temperance Conference. A further motion considered enforced widowhood as an infringement of the rights of women and recommended that all obstacles in the way of the marriage of widows should be removed. It is not generally known what a large proportion of girls under ten years of age are married. The census gives a rate of 115 per 1000 females and for child widows 6 per 1000 females. This shows that 1 in about every 9 female children is married before ten years of age and that about 1 in 20 of these infant marriages is followed by child widowhood In Bengal the rate is much higher—nearly 1 in 5 of the female children being married—and in Behar the proportion rises to 1 in 3, with child widowhood about 1 in 18 When it is remembered that this widowhood is enforced in most cases for life the injustice and evil will be manifest

Jan 14th

THE HOUSING PROBLEM AT BOSTON, U S A

(FROM OUR SPECIAL SANITARY COMMISSIONER)

MY first attempt to investigate the question of working class dwellings and of the housing of the American poor was made in Boston One of the local papers, the *Boston American*, sent a member of its staff to interview me and he at once inquired what I thought of the Boston slums This enterprising journalist was somewhat disappointed on hearing that I had not thought about them at all and this for the simple reason that I had not seen them If, however, he would take me round and show me the worst quarters of the town then I would be pleased to say what I thought about them. In this manner I secured the assistance of a pleasant guide and companion First we visited Salem street which is the Petticoat-lane of Boston Here the population seemed somewhat dense and the dark recesses in many of the small shops looked forbidding but there was nothing very different from what may be seen in Europe—in, for instance, the Jews' quarter of Amsterdam In Martin street close by we found a house with only one closet which was certainly insufficient for the large number of inhabitants but it was clean and well flushed In the basement there was, in the back part of the house, a very small room with no window opening to the outside and here lodgers slept, though for want of light and ventilation it was not fit for habitation The tenement in this basement consisted in all of three rooms and the rent charged was £2 8*s* per month For from 25*s* to 30*s* a month better accommodation could be obtained in London and even in Paris Another tenement which we visited had two good rooms and two dark back rooms and the rent was £3 per month

From the Jews quarter we went to the Italian and Portuguese district In Keith's alley overcrowding was the chief grievance, though this is not surprising considering the high charges made for rent One of the tenements was ventilated by an irregularly shaped, small shaft which apparently had not been cleaned out for years On the other hand, it was a pleasure to see here, as I have seen among the poor of Italy the domestic cleanliness the love of white and tidy linen which are the pride and joy of the Italian housewife Here in one of these tenements, which I was assured formed part of the slums of Boston, we admired the white bed linen and the embroidered pillow cases of a bed that stood in the one living room Close to the bed on the stove the dinner was in course of preparation, giving off aromatic odours which showed that the Italian housewife was as artistic in the selection of her flavouring ingredients as she was in the decoration of her household linen In Page court, off North street, there were signs that the scavenging had been much neglected There were barrels full to overflowing with ashes and garbage, so that dirty paper and other light refuse were blown about the yards Then a number of rain water pipes from the roofs had split open, some for their whole length The aperture gaped and was widest about half way from the top The rain water coming down such pipes must escape and render the house wall very damp Rents here were equally high in spite of this neglect and the back courts or openings were very erratic in shape and often not large enough to give sufficient air and light In Power s-court and other places there are old houses with such very narrow and small windows that they cannot sufficiently light the rooms On the other hand, it was satisfactory to note that many of the inhabitants kept these windows open as if they appreciated the advantages of having a plentiful supply of fresh air Perhaps a small window that is constantly open is better than a large one that is always shut.

At a dispensary where the poor of this quarter obtain medical relief I was told that during the last three years they had patients belonging to 18 different nationalities Indeed, while visiting these poor quarters it was difficult to believe that I was in America In any case I felt much more at home than my guide who, being an American, had not my knowledge of these various European people He was particularly impressed by the savoury cooking that was going forward in the poorest dens which we visited, whether the tenants were Portuguese, Italians, or Pol [illegible] find any extensive prevalence of [illegible] were details that required remed [illegible] there were three tenements with a family in each and only one closet between them Here the backyard had planks of wood for pavement but the wood was in many places eaten away Mud and dirt oozed through and egg shells and other refuse lay about The closet was dirty , nevertheless, when people stood on the seat they automatically pressed down a knob which produced a good flush Then there were basement stairs which were dirty and dark Nevertheless, and in spite of the details mentioned, it was only when we at last came upon the Italian organ grinders' quarter that we found something worthy of comparison with a European slum

Undoubtedly this Italian court was at once the worst and the only picturesque place we were able to discover Here the houses or huts are built in a most irregular manner There are terraces for roofs and other smaller houses rising from these terraces The top house of all is so small and narrow that the attic where many organ grinders sleep seems more like a passage under the roof The space where it is possible to stand upright is barely three feet wide and then the slanting of the roof makes it necessary to stoop to reach the beds These are placed as far as possible under the roof which is certainly not more than two feet above the sleeper as he is lying in bed If this roof is not very perfectly tiled the bedding must get wet when it rains Here at last we got the real stuffy smell of the genuine slum While the highest parts of this strange conglomeration of houses or huts was thus so forbidding and foul, the very deep basement or cellar at the lowest and opposite extremity was not particularly inviting Here there was an oven and beyond in the dark far side of this large sort of cellar there was a dirty long table where the ' boarders ' of the barrel organ fraternity dine Doubtless they dine well for the price they pay—namely, 10*s* a month for sleeping in the attic and £1 12*s* a month for feeding in the cellar Just outside the door and steps leading to this cellar there are two foul, dirty, malodorous closets and a broken urinal Fortunately, the garlic laden fumes and the scent of bay leaf and thyme which escaped from the well-flavoured stew simmering on the oven below provided a [illegible] guide, I asked the organ grinders which restaurant they patronised when on fete days or other special occasions they indulged in a particularly good dinner Having thus obtained a likely address we proceeded to lunch at the restaurant that enjoys the special patronage of Italian organ grinders As a result my American companion declared that he would forthwith bring his wife to this restaurant of organ grinding renown so that she might learn how to cook Undoubtedly the tasteless cold storage meat eaten in America requires to be treated with the resourceful ingenuity of the Latin races in order that it may be rendered palatable

With the exception of this small group of strange structures inhabited by organ grinders it did not seem to me that the housing problem at Boston had reached the acute stage attained in many European towns, so far at least as the sanitary phases of the difficulty are concerned There is undoubtedly a difference in the death rates of various localities but I hardly think that this is due to any very striking structural defect in the dwellings It is rather the result of poverty, of racial predisposition and of overcrowding Of course in this respect it is the tenement houses that are the worst Fortunately, measures are being taken to put a stop to the " sky scraper nuisance It is only in the business streets that the building of very lofty houses will be allowed In residential quarters it will not be permitted to build a house that measures in height more than one and a half times the width of the street. Therefore, if a street is 30 feet wide no house must be more than 45 feet high. In old quarters instead of pulling down houses so as to widen the streets it will, it is thought, be less troublesome and less expensive to remove some of the upper floors of the houses so that they shall not be higher than accords with the width of the street. This, however, is not at present the law, but a Bill to that effect is to be submitted to the State legislature.

Boston seems to be going through an experience similar to that acquired in England some 50 years ago. Thus from 20 to 30 years ago the entire housing problem it was believed would be solved by our old acquaintance the 5 per cent. philanthropist. A coöperative building society intended to erect model tenements and to content itself with 5 per cent. interest on the capital invested. The society also took over old and defective dwellings and improved them. But even under these conditions it had to charge £3 a month for tenements of three rooms; and some four years ago the managers came to the conclusion that in spite of such high rents this was no longer possible, at least not in the central and congested districts. The society said that the present building laws enforcing the employment of steel beams, plaster walls, and, in fact, strict fireproof conditions, made it too expensive to build. The question now discussed is whether it is a fact that nothing can be done so as to build model tenements at comparatively low rentals and yet yielding 4 or 5 per cent. profit. Private enterprise in Boston has reached the point attained in London many years ago and is now no longer desirous to speculate in such matters. Yet the municipality of Boston is not attempting to grapple with the difficulty. It refuses to own any land except parks for the people. Instead of acquiring land and itself building tenement houses, as the County Council of London and so many other towns in England have done, the municipality of Boston is only seeking to modify the law so that cheaper—that is to say, more dangerous—houses may be erected. It is proposed that the restrictions to make the houses fireproof shall be withdrawn. Thus, cheaper material being allowed in the construction of "model" dwellings, the philanthropists, at the risk of roasting their tenants, will after all be able to make their 5 per cent. Boston has not yet reached that stage of evolution in municipal matters which was attained in London and many large British towns some years ago. Its municipality does not realise that certain things have to be done, if not by private enterprise then by public enterprise; if not at a profit then at a loss; and that the greatest loss of all is to leave them undone. This applies with particular force to insanitary areas.

The prevalence of disease at Boston is not, however, intimately associated with any special quarter or area. Disease follows the race rather than any particular feature in sanitation. Thus tuberculosis is much more prevalent in the tenements inhabited by the Irish and pneumonia is more common in tenements occupied by other races. Undoubtedly the chief difficulty is with the new arrivals, immigrants who are not yet in receipt of the higher rate of wages paid in America and who consequently cannot afford the high rents charged. However, in spite of the immense crowd of immigrants who land there the housing problem at Boston has certainly not yet reached the acute stage which prevails in many of the seaport towns of Europe.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Victoria University: Opening of the New Pathological Laboratory.

THE formal opening of the new pathological laboratory in connexion with the Victoria University marks an occasion important in its relation to bacteriological research and to the bearing of increased and increasing knowledge on the public health. The laboratory is situated in York-place, near the new infirmary, and has been planned so as to be well adapted for its purpose. It is two storeys in height, about 160 feet long by 60 feet deep, with outbuildings 136 feet by 16 feet. The chief characteristics are unlimited light and the installation of important and yet simple appliances. As one of the local reports says, "it will be, when more funds are received, better able to cope with public health work than any other laboratory in the kingdom." Professor S. Delépine has a staff of 13 qualified assistants, five students, one secretary, and six servants. Last year over 100 sanitary authorities, representing the public health of between five and six millions of people, made use of the laboratory "in cases or outbreaks of consumption in man and animals, anthrax, typhoid, malaria, food poisoning, glanders, fowl cholera, rag-pickers' disease, Asiatic cholera, plague, and noxious properties in all sorts of food." In addition to this the laboratory dealt with sterilisation and disinfection, methods of filtration, and many kindred questions. Reports are made by the staff on morbid products for public authorities and medical men. Bacteriology is taught to candidates for the diplomas of public health, to chemists, veterinary surgeons, and teachers in agricultural or dairy schools; investigations and research work are always going on in relation to the public health work and to cancer (in connexion with the Christie Hospital), while medical men often conduct investigations bearing on the cause and prevention of disease. Of course, all this entails expense and more pecuniary help is desirable if the wide field of usefulness lying open is to be cultivated thoroughly. As a local paper puts it, "a few benefactors" are needed "who are willing to decrease the death-rate of the future by paying now for the knowledge of how to prevent disease." Earl Spencer, the Chancellor, presided at the opening ceremony which was performed by Mr. W. J. Crossley, the chairman of the advisory committee, who it may be remembered gave munificently towards the establishment of the sanatorium for consumption in Delamere Forest in connexion with the Manchester hospital for that disease. He was presented with an ornamental key by Professor Delépine who described the remarkable growth of the work of the laboratory during the last ten years and stated that he had received letters of commendation from many distinguished men of science, including one from Lord Lister who said that the enterprise would be of immense service to Manchester and its neighbourhood and would bring additional renown to the Victoria University. In his reply Mr. Crossley stated that a large portion of the study and investigation carried on in the laboratory would tend towards the prevention of disease which was better than cure. "The layman's share of the work was to contribute to the funds, not to stint the means of study." The building cost over £6000 and the equipment £700, and this was largely unpaid, so that further sums were required for full equipment. The Vice-Chancellor, Dr. A. Hopkinson, referred to Professor Delépine's long years of work towards the establishment of this laboratory and added that Mr. Crossley had given much larger help than he would allow to be mentioned. The Lord Mayor, in moving a vote of thanks to Mr. Crossley, observed that nearly half of the work of the laboratory had been done for the corporation. Dr. Arthur Ransome seconded the vote of thanks and Professor Calmette of Lille, who spoke in French, humorously urged that if the laboratory were self-supporting it would imply a great prevalence of disease. On behalf of the Pasteur Institute of Lille and of Paris he congratulated Professor Delépine on his work.

"Held by Electricity."

An accident that took place recently at the Burnley electricity station illustrates the dangers always accompanying electrical developments. The staff and members of the electricity committee were witnessing the trial of an electrically driven air-compressor. After running for some little time on a wood floor it was proposed that it should operate on one of the dynamos. As soon as the engine driver put his foot on the metal floor plate he was thrown down. Mr. Birkett, the electrical engineer, ran to his assistance when his hands touched the metal drawbar of the compressor and he too was flung to the ground with great violence. "The whole of the current for tramway traction purposes was passing through the compressor" and Mr. Birkett could not loosen his hold of the drawbar. He got on his knees, received another heavy shock, and became unconscious. An assistant fortunately ran to the switchboard and broke the circuit, also receiving a severe shock, and Mr. Birkett was released. The engine-driver, in the first place, got a severe shock but Mr. Birkett was more seriously hurt. "Holes were burnt through his trousers into the flesh of his legs" and one knee-cap was seriously injured.

Lead in Mossley Water.

Numerous cases of lead poisoning have recently occurred in the borough of Mossley. The chairman of the public health committee recently said that "from what he had been told they in Mossley were receiving the water against which Saddleworth people had so bitterly complained on account of the sickness and lead poisoning it caused." He cautioned householders before using water for domestic purposes to run off a quantity first. This caution, though often repeated, cannot be repeated too often, for haste, carelessness, and idleness cause its frequent neglect. The special liability to contamination by lead of moorland surface water is well known but often forgotten and has to be set against the good from the pure fresh breezes that come from the moorland gathering grounds.

Jan. 31st.

LEEDS.

(FROM OUR OWN CORRESPONDENT.)

The General Infirmary at Leeds.

THE statement of admissions and attendances for the year 1904, which will be incorporated with the annual report, shows an increase of work in almost all departments. The number of beds which are always ready for occupation is 395 and it has seldom been the case that more than 10 per cent. of these have been unoccupied. Attached to the infirmary is the Ida Semi-Convalescent Hospital at Cookridge, some four and a half miles from the infirmary. This has 46 beds and is of great service in affording accommodation to patients who, especially after operation, require skilled nursing combined with the benefits of a convalescent home. It is reserved exclusively for patients who have been treated at the infirmary. The total number of patients treated as in-patients during 1904 was 6873, of whom 356 were in the infirmary on Jan. 1st. Of the 6517 admitted 1191 were medical, 4044 were surgical—including 909 accident cases—730 were ophthalmic cases, 219 were aural cases, and 333 were admitted to the gynæcological wards. The average number of patients in the wards was 355. The number of deaths was 477, giving a death-rate of 6·94 per cent., but excluding 123 deaths which occurred within 48 hours of admission the mortality was 5·17 per cent. In the out-patient department close upon 40,000 new patients were attended to. These comprised 12,769 medical cases, 5462 surgical cases, 495 gynæcological cases, 4569 ophthalmic cases, and 1853 aural cases. Among the medical patients, but not included in the above figures, 688 new skin cases and 152 throat cases were separately dealt with by the out-patient physicians. The number of casualties amounted to 10,170. The new semi-convalescent home at Cookridge is approaching completion. This, which is to be called the Arthington Hospital, will, it is expected, be built and equipped entirely out of the fund given by the late Mr. Robert Arthington for the purpose, but its maintenance will involve an extra expenditure of about £2000 per annum. The design and elevation of the new buildings are very similar to those of the Ida Hospital which it adjoins. The two hospitals will, indeed, be practically one and the administration department, kitchens, &c., will be common to both. When the building is completed the infirmary will have at its disposal about 100 beds for patients who are described above as forming the semi-convalescent class.

Hospital for Women and Children.

Largely as the result of the increase in the work consequent on the opening of the new buildings and the institution of the lying-in department, some changes of importance have been arranged in the constitution of the honorary staff of the Hospital for Women and Children. The acting staff consists at present of three honorary surgeons who until a few months ago attended both to women and to children. In March an assistant physician was appointed to see the medical out-patients in the children's department and a new appointment is to be made of an assistant surgeon for children whose work will also be confined to the children's department. In making this new appointment and in filling up either post in the event of any vacancy occurring the electors will doubtless be influenced in their choice by considerations of special knowledge of the medical and surgical diseases of early childhood, for it is not intended that the assistant surgeoncy for children should carry with it any claim for promotion to the full staff on a vacancy occurring. It has also been determined that on a vacancy occurring in the full staff, which at present consists of three, the honorary surgeoncies shall be reduced to two and that an assistant surgeon shall be appointed who will assist the surgeons in their gynæcological and obstetric work and act as their deputy should occasion arise.

Leeds Public Dispensary.

Applications are invited for the post of honorary pathologist. The new officer will be in charge of the clinical laboratory and will have a seat on the faculty of the dispensary and on the board of management. The appointments in connexion with the new dental department have *just been made. As honorary dental surgeons there have* been appointed Mr. J. H. Carter, Mr. W. E. Margetson, Mr. J. E. Greaves, Mr. P. T. Leigh, Mr. W. Marston, and Mr. A. G. G. Plumley. The honorary assistant dental surgeons are Mr. Stephen D. Hey, Mr. James N. Nicol, Mr. Henry Perkin, Mr. Cecil G. Riddett, Mr. David Saville, and Mr. R. Littlewood Young. Mr. F. Sherburn at the end of his 20 years' service as honorary dental surgeon becomes consulting dentist to the institution.

Prosecutions for the Sale of Watered Milk.

The stipendiary magistrate has imposed fines of 40*s.* and costs in two cases and bound the defendant in the third case in the sum of £5 to come up for judgment if called upon and exacted an undertaking from him to abandon the trade. The amount of water in the three cases was respectively 14, 32½, and 11½ per cent.

Poisoning by Coal Gas.

Two cases of poisoning by coal gas are reported from Batley. From the account of the coroner's inquest it appears that the manager of the gasworks and a striker were found dead in the coal storage shed. They were found close to an upright four-inch gas main which connected the two purifiers and was provided with valves where it opened into each. It was not quite clear how the accident happened but it is supposed that the first victim was the striker and that the manager met his death in an attempt to rescue him. The gases which would escape if the valves were opened would be sulphuretted hydrogen, carbonic acid gas, and carbon monoxide. Mr. H. Keighley, who made the necropsies, gave evidence to the effect that death in each case was due to carbon monoxide, the presence of which in the blood was shown by the characteristic spectroscopic appearances.

Jan. 31st.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

Cardiff Infirmary.

FIVE years ago the governors of the Cardiff Infirmary inaugurated a scheme for providing necessary permanent additions to the institution, the principle of which lay in the publication of the specific requirements, together with their estimated cost. Several private individuals have subscribed the entire cost of certain of these requirements and altogether no less a sum than £18,000 has been expended. The latest addition to the infirmary is an electrical pavilion, the cost of the structure of which (£2000) has been paid by Mrs. W. H. Martin, and special subscriptions of £500 have defrayed the cost of the furniture and fittings. The pavilion, which was formally opened by Sir William Preece, F.R.S., on Jan. 26th, is a one-storey building placed in a central position on the main corridor of the infirmary. The inside walls are lined with pale olive-green crystopal tiles and the floors are paved, like that of the operating theatre, with terrazzo. The building includes a waiting room, two water-closets, a Finsen lamp room with dressing room, an x ray photographic room, a photographic room for developing, and a room for general electrical treatment. The installation of appliances is very complete, especially as regards x ray apparatus, and also includes a d'Arsonval-Gaiffe high-frequency apparatus which works directly without any interrupter from the town mains, appliances for stereoscopic and localising purposes, a

16-inch induction coil with adjustable primary winding (Dr. Walker's method) with Wehnelt electrolytic interrupter, to be worked from a motor generator giving 65 volts, a Finsen lamp, and a St. Bartholomew's Hospital lamp for ultra-violet rays. The department is in the charge of Dr. William Martin, one of the honorary assistant surgeons, who is himself the inventor of lead glass shields fitting on to focus tubes. He has also made ample provision for the protection of operators and patients from the deleterious effects of the x rays by means of a large lead screen to protect the whole body of the radiographer, a lead box with adjustable diaphragm for screen examinations, and lead glass shields. Colonel Bruce Vaughan, the chairman of the house committee, is very largely responsible for the acquisition of this pavilion.

The Teeth of School Children.

A valuable report has just been issued by Mr. E. Rice Morgan, medical officer to the Swansea education committee, in which he gives the result of an examination which he recently made of the teeth of some of the boys and girls attending five schools in the upper division of the borough. Among 151 boys examined only five, or 3·3 per cent., had no unsound teeth and of the remaining 146 boys each had on an average 3·7 decayed teeth. Among the 144 girls examined there were six, or 4·1 per cent., with all their teeth sound, while the remaining 138 had on an average 3·2 teeth which were unsound. Mr. Morgan is evidently of opinion that dental surgeons might with advantage be appointed to look after the teeth of the school children. He does not, however, advise this for the present but suggests that in the first instance parents and scholars should be supplied with printed rules for the preservation of the teeth of children. In the rules which he has drawn up he points out that sound teeth are necessary for good mastication and that good mastication is requisite for good digestion, that food left on the teeth ferments and becomes acid, thus producing decay, and that the teeth should be cleaned night and morning with a tooth brush and a simple tooth powder.

Carmarthen Asylum.

The committee of visitors of the Joint Counties Asylum at Carmarthen has increased the salary of the medical superintendent (Dr. Edwin Goodall) from £600 to £700 per annum. Dr. Goodall has held his present appointment for nearly 11 years.

Motor-cars for County Officials.

A committee of the Glamorgan county council has recommended the purchase of a 12-horse power motor-car at a cost of £475 for the use of the county surveyor. The salary of the surveyor of the Carmarthen county council has been increased in order that he may use a motor-car for travelling about the county.

Meteorological Records at Bath.

Ever since he was appointed medical officer of health of Bath, eight years ago, Dr. W. H. Symons has devoted a great deal of time to the investigation of the meteorological conditions of the city and at the last meeting of the West of England and South Wales branch of the Incorporated Society of Medical Officers of Health he laid before the members some of the results of his observations. As an illustration of the necessity for checking the records of an earth thermometer he stated that on one occasion he found that a four-foot instrument in one part of the public gardens registered nine degrees above the temperature registered elsewhere and upon investigation he discovered that the waste water from the hot baths was carried off in a culvert a few feet away from where this thermometer had been placed. Dr. Symons is not very sanguine of the possibility of making accurate records of the density of fogs and considers that the fog gauge made of alternate white and black stripes of varying width, though suitable for the very opaque small-grained London fog, is quite useless in the estimation of the coarse-grained fog of the country. He proposes a scale based upon the limit of visibility and for this purpose notes the distance of various objects from the point of observation. For example, if the outline of a hill known to be six miles away can be seen but not beyond he records F 1; if an object three miles distant can only be seen then F 2 is recorded; and if an object one and a half miles distant is only visible then F 3, and so on. He thinks the geological and physiographical conditions have to do with the formation of fog. The very careful meteorological observations made by Dr. Symons, which include the amount of sunshine, the direction and the pressure of the wind, and the amount of evaporation going on, ought to be appreciated to the full in a town the popularity of which is dependent upon physical conditions.

Bath Eastern Dispensary.

The annual report of the Bath Eastern Dispensary, an institution which was established in 1832, states that 2724 visits were made to patients during 1904 and that the expenditure of the dispensary was £655, causing a deficit on the year's working of £52.

Plymouth Workhouse Infirmary.

At the meeting of the Plymouth board of guardians held on Jan. 26th a long discussion took place concerning the proposed scheme for providing a new infirmary at an estimated cost of £56,000. Eventually it was decided that only women's general wards should be erected to accommodate 104 patients at a cost of £9450.

Jan. 30th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

The Majority of the Students' Representative Council of the University of Edinburgh.

THE Students' Representative Council of the University of Edinburgh has attained its majority and, as was suitable at such an important date, it has been marked by special proceedings. On Friday night the students held a torchlight procession through the city which passed off successfully and was witnessed by many thousands of spectators. On Saturday night a dinner was held in the University union under the chairmanship of the senior president of the council, Mr. H. V. Rabagliati. The company numbered about 130 and included various distinguished persons and not a few of those who had taken an active part in the establishment of the council over 20 years ago. The Solicitor-General for Scotland, Mr. Dundas, K.C., who has just been raised to the Scottish bench, proposed the toast of the evening and dealt with the history of the formation and the work of the Students' Representative Council. The chairman responded to the toast and urged upon students to take more interest in the council as being the centre of University life. The Lord Advocate proposed the toast of "Alma Mater" and Principal Sir William Turner replied.

Researches into the Etiology of Carcinoma.

An interesting paper by Dr. W. Ford Robertson and Mr. H. Wade on plasmodiophora in cancer appeared in THE LANCET last week. During the week Dr. Robertson invited a number of his friends to a private demonstration of sections and cultures which was largely taken advantage of and much appreciated. On Thursday evening the work was submitted to the Edinburgh Pathological Club where it was fully discussed. This work is such a definitely new departure on previous methods that more will no doubt be heard of it.

Jan. 30th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Dispensary Medical Officers and the Local Government Board.

THE important case of Keelan *v.* the Local Government Board (which was reported in THE LANCET of Dec. 17th, 1904, p. 1757, and in which the legal right of the Board to amalgamate Collon No. 1 and Drumcondra dispensary districts (Co. Louth) with Collon No. 2 and Dunleer districts was contested at the instance of Mr. M. Keelan and Mr. M. Caraher) was reopened on Jan. 30th in the Court of Appeal before the Lord Chancellor, Lord Justice Fitzgibbon, Lord Justice Walker, and Lord Justice Holmes. It will be remembered that the Court of King's Bench refused to set aside the order of the Local Government Board by which one dispensary district was entirely done away with. The importance of the appeal is due to the fact that it is really a conflict between the Irish Medical Association and the Local Government Board and the Board's view of its gravity is shown by its having briefed for each trial both the Attorney-General and the Solicitor-General in addition to its own counsel. The case is now being heard.

Appointment of Coroner for Belfast

At a special meeting of the city corporation of Belfast held on Jan 30th Dr James Graham was appointed city coroner of Belfast at a salary of £650 per annum It would appear that the Act of Parliament lays down that the coroner shall be paid by fees but to get over this it has been arranged that all fees received on account of the office over and above the sum of £650 shall be refunded to the corporation

Purdysburn Infectious Diseases Hospital

A number of years ago contrary to the views of the medical profession in Belfast, the city corporation decided to build an infectious diseases hospital at Purdysburn, about *three miles from the city and close to the new asylum* Apparently the corporation never considered the question of the drainage of either institution and quite recently it was discovered by the appearance of pipes on the roads that it is now proposed to convey the sewage of both the infectious diseases hospital and of the asylum directly into the city sewerage system and to bring it right through the main drains of the city Naturally this has aroused great opposition and a deputation of ratepayers who waited on the public health committee were assured that there was no danger as the sewage would be disinfected This statement, however, has only stimulated the ratepayers to still more determination and at a meeting held on Jan 30th it was decided to send a deputation to the city council in reference to the matter Those who object to this new departure on the part of the city fathers say 1 Why are patients with infectious disease taken away to a hospital right out of the city and then their dejecta brought back again into the city? 2 The scheme will cost £6000, for the pipes have to be brought at least a mile to join the main city sewers and a pumping station will have to be established and there will be an annual up keep 3 In exceptional periods when parts of the city are flooded it was proved that objectionable matter was as a result deposited, a state of matters much more serious in the case of sewage coming from an infectious diseases hospital 4 That it is unwise to depend on a few workmen for the disinfection of sewage coming through the city from an infectious diseases hospital The question at issue is whether there is any plan of disinfection of the sewage which will be sufficient, the public health committee says that there is but it has not yet stated what method it proposes to adopt Apart from everything else it shows wonderful want of forethought that the committee should not have arranged *definitely as regards the disposal of the sewage* from a large infectious diseases hospital before undertaking the erection of such an institution

The New City Hall, Belfast

Great uneasiness prevails in Belfast as to the total absence of business capacity now shown by the corporation owing to the extraordinary revelations made public last week at an inquiry held by the engineering inspector (Mr P C Cowan) of the Local Government Board regarding a further loan for the new city hall The original contract was £150,000, £300 000 have been already expended *and now, after the lapse of seven years, more money* is wanted for furnishing As Mr Cowan (who commented very severely on the matter) could get nothing but loose figures and estimates on the part of the committee of the corporation as to what the ultimate cost of the building would be, he adjourned the inquiry to March when he will require a clear definite and final statement of the total cost of this wasteful piece of corporate expenditure It is no wonder that so little progress is being made in public health reform in Belfast when it came out at this inquiry that £8000 were to be squandered in the furnishing of the main council room in this ' House of Lords (as Mr Cowan the inspector, called it in contempt) with chairs reckoned to cost £50 each for the city fathers

BERLIN

(FROM OUR OWN CORRESPONDENT)

Alleged Communication of Syphilis to a Horse

AT a recent meeting of the Berlin Medical Society Dr Piorkowsky showed a horse to which he had given an intravenous *injection of blood serum obtained from patients* suffering from syphilis in different stages The injection was made into the jugular vein and several weeks afterwards a papular eruption appeared on the neck and the breast of the horse together with a swelling of the glands The interval between the injection and the appearance of the eruption corresponded to that elapsing in the human subject between primary infection and the development of secondary symptoms Dr Piorkowsky was of opinion that the eruption was syphilis In the ensuing discussion Professor Lassar adopted this view on the ground of the microscopical examination of the eruption, which, he said, presented features very similar to those observed in syphilis Dr Aronson, however, stated that eruptions having the characteristics in question were often observed in horses after the *injection either of albuminous substances or of extracts of* bacteria and that they had nothing to do with syphilis Dr Benda, Dr Hoffmann, and Professor Brieger opposed Dr Piorkowsky s views on anatomical grounds The general opinion of the meeting was that the communication of syphilis to the horse was not proved by Dr Piorkowsky's experiments and that no inferences as to the production of an antitoxin for the treatment of syphilis could be founded on them

(FROM OUR OWN CORRESPONDENT)

A New Bacteriological and Pathological Laboratory

Dr George Charlton of Montreal has been appointed by the Government of the North West Territories of Canada to [illegible] of cattle and horses, as the [illegible] siderable loss from a disease known as swamp fever which is rapidly fatal to horses The College of Physicians and Surgeons of the North West Territories will also benefit by the establishment of the new laboratory, as Dr Charlton will conduct investigations there in regard to epidemics of diphtheria and typhoid fever Dr Charlton has recently returned from Europe where he has been working in various laboratories since his connexion with the pathological department of McGill University some few years ago

Montreal Hospital damaged by Fire

Montreal s fine hospital the Royal Victoria was damaged by fire to the extent of $30 000 early on the morning of Jan 14th No patients were removed from the wards but everything was in readiness for such an emergency The governors have received a cable from Lord Strathcona, Canadian High Commissioner in England, that he will bear all the cost of restoring the burned portion of the building The report of this institution for November, 1904, shows that 245 patients were admitted during that month, that 229 were discharged and that 11 died In the outdoor departments there were 764 medical cases 407 surgical 467 ophthalmological 76 gynæcological, and 374 laryngological, making a total of 2088

Notre Dame Hospital, Montreal

At the annual meeting of the board of governors of Notre Dame Hospital Montreal, which was held in December last, it was shown by the annual report that during the last official hospital year the number of patients admitted into the institution reached a total of 2226, of whom 1313 were men and 913 were women Of the indoor patients 1919 were discharged recovered or improved, 166 left the hospital unimproved or recognised incurables while 156 died in the hospital The average stay of each patient in the hospital was 18 days In the outdoor services [illegible] given In the pharmacy 26 000 [illegible] The ambulance made 1437 c[illegible] hospital $1 09 per day The total expenditure amounted to $43 824 63 and the total receipts to $41 742 05, thus leaving a deficit of over $2000 The new contagious diseases hospital in connexion [illegible] good progress and will be ready [illegible] this year It will have accommo- [illegible] will be modern in every respect

Annual Report of the Montreal League for the Prevention of Tuberculosis

The Montreal League for the Prevention of Tuberculosis has been at work now for upwards of 18 months, the reports of the first cases of consumption being received on June 1st, 1903. Reporting of cases of consumption to the league is, of course, optional, the object being to educate and to instruct those afflicted as to the regular ordering of their daily lives. Where the cases are advanced, where destitute and neglected, they are sent to the home for incurables; in incipient cases an effort is made to send the patients to the country but lack of financial support has somewhat crippled the league in its work. An interesting and important investigation has been made by the league in connexion with the deaths from meningitis in children reported to the city health department. In 1903 there were 248 deaths among children under five years of age from meningitis in Montreal. In almost every case investigation established the fact that in the homes of the patients there was living someone with consumption and the records at the health office showed that fully 90 per cent. of these deaths were tuberculous. During the 18 months of the existence of the league 300 cases have been reported to it, the youngest being five and the oldest 70 years of age. Of the 300 cases information has been received of the death of 136. Of this number 85 were between the ages of 16 and 36 years. The work of the inspector of the league up to the issue of the report was as follows: visits made to different cases, 1667; 9000 cuspidors distributed; a large quantity of pamphlets distributed; 500 houses disinfected; and 3000 wall cards placed in 326 public and private institutions for the instruction of the inmates.

Obituary.

AMBROSE BIRMINGHAM, M.D. R.U.I., F.R.C.S. IREL.,

PROFESSOR OF ANATOMY IN THE CATHOLIC UNIVERSITY MEDICAL SCHOOL, DUBLIN.

Professor Ambrose Birmingham died in Dublin on Jan. 23rd at the untimely age of 41 years, after an illness which he bore with cheerfulness and, indeed, with heroism. He was born in the West of Ireland and belonged to a family in which no less than five brothers became members of the medical profession. His early education was received at St. Vincent's College, Castleknock, and his professional studies were pursued at the Catholic University Medical School in Dublin. He took the diploma of L.R.C.P. Irel. in 1885 and having also become an undergraduate of the Royal University of Ireland he graduated there as M.B. in 1887 with the additional distinction of obtaining first honours and an exhibition. In 1892 he proceeded to the degree of M.D. in his university and in 1897 he was admitted F.R.C.S. Irel. At an early period in his career he was appointed demonstrator of anatomy at the medical school of the Catholic University, and then assistant to Dr. (now Sir) Christopher Nixon who has the merit of having been the first to recognise his special ability. In 1888, when Sir Christopher Nixon on the death of the late Dr. Lyons accepted the chair of practice of medicine, Dr. Birmingham was appointed professor of anatomy and registrar to the medical school and made a visit to the University of Edinburgh. On his return to Dublin he became a Fellow of the Royal University of Ireland and proceeded to devote all his ability and energy to his special subject and to the welfare of his medical school. In a short time he developed an extraordinary aptitude for organisation and business and with his clever lectures the number of students quickly increased from 100 to the 300 who marched three deep in his funeral procession on Jan. 26th. Yet with all this work on his hands he found time to devote to investigation and to the purely scientific side of his profession. A long list of his original papers and communications is to be found in the Medical Directory under his name. Perhaps the most important of these was his contribution to the "Textbook of Anatomy" by his friend Professor D. J. Cunningham, to which he supplied the article on the Abdomen. Moreover, his paper on Cranio-cerebral Topography with Special Reference to the Mastoid Region of the Skull is of permanent practical value. For many years Professor Birmingham had suffered from colour blindness. About two years ago the continuous strain of his many undertakings proved too much and though he was partially restored by rest and a tour on the Continent he was never again the same man. His health unhappily broke down just as he was doubtless about to obtain the distinctions to which his brilliant and arduous work entitled him. Professor Birmingham was always modest and unaffected; he was universally esteemed by his colleagues, while he was justly admired and almost venerated by the crowds of pupils whom he taught so successfully and to whose advancement he really sacrificed his valuable life.

At the Catholic University School of Medicine, the Dean of the Medical Faculty (Sir Christopher Nixon), in addressing the professors and students, said: "I have never had to undertake so painful a duty as that which falls to my lot to-day in referring to the death, in the prime of life, of my former pupil, colleague, and devoted friend, Professor Birmingham. In the full vigour of a brilliant and well-trained mind, after passing the period of storm and stress through which all scientific workers must pass, as through a fiery ordeal, when all that brings fame and fortune is almost within one's grasp, 'death breaks the vital chain,' and robs both him and us of the fruits for which the seed had been so industriously sown. The whole thing is unutterably sad, too sad, indeed, for empty expressions of regret. Just 18 years ago Professor Birmingham succeeded me as professor of anatomy, and from that time up to the present he held a dual position in the school. He was responsible for the working of the anatomical department, and as registrar upon him devolved the organisation of the school as a whole, the several details of its financial arrangements, and in many respects the work for which I, as dean, am nominally responsible. In every phase of his work he was brilliantly successful and amidst all his labours he found time, with those elements of genius with which he was richly endowed, to make for himself a name distinguished amongst the ablest men of his own special science as a man of original powers of observation and research. If I might in a brief way analyse Birmingham's splendid abilities I would do so under three heads—as a teacher, as an original observer, and in reference to those qualities which made his personality so attractive to all who knew him. As a teacher he was the nearest approach to the ideal that I have had experience of. With the most thorough knowledge and grasp of his subject he possessed the rare gift of making it transparently clear, and by a bright and vivid description invested it with such interest as to excite the rapt and sustained attention of his class."

GEOFFREY HETT, M.D. EDIN., M.R.C.S. ENG.

THE death of Dr. Geoffrey Hett of 41, Westbourne-park-road, which occurred on Jan. 25th, in his sixty-first year, came as an unexpected blow to his friends. Born in Lincolnshire, he was educated at Merchant Taylors' School, then at King's College and the University of Edinburgh. After serving as house surgeon successively to the Lincoln dispensary and hospital he settled in London and spent most of his life as a Bayswater practitioner. In his early days he did good service as honorary secretary of the Royal Medical Benevolent College. He was also a contributor on medical subjects to the *Saturday Review*, under the editorship of his friend Mr. Walter Pollock, and had a special practice among literary men of that set. For the greater part of his life he was one of the officers of the Westbourne Provident Dispensary, the subscribers to which experienced his unfailing kindness and care not less than his better-class patients. Dr. Hett was a remarkably active man who, having turned 60 without a grey hair, still kept up his rowing and swimming. In youth he had been an energetic football player; in later days he would spend a holiday in walking to Brighton and to the last he made one of the small band of winter bathers in the Serpentine. His sudden death from heart failure was, therefore, a most painful shock to his family, with whose sorrow many will sympathise. One who has known him intimately for the greater part of his life writes that he cannot remember his ever saying a harsh or unkind word and few who came in contact with him could fail to be impressed by a singularly genial, unselfish, and serene nature. The first part of the burial office was said at St. Mary Magdalene's Church, Paddington, by the vicar, the Rev. W. H. Bleaden, a large congregation being present. The committal portion of the service was taken by the Rev. James Dixon, vicar of Willesden, an old friend and a former member of the dispensary committee. Dr. Hett leaves a widow, one daughter, and three sons, the eldest *of whom is a member of the medical profession*

DEATHS OF EMINENT FOREIGN MEDICAL MEN — The deaths of the following eminent foreign medical men are announced —Dr Guido Bodlander of Brunswick, who was formerly assistant to Professor Binz, the Bonn professor of pharmacology —Dr I M Lvoff, *privat docent* of midwifery and gynæcology in the University of Kazan

Medical News.

UNIVERSITY OF OXFORD. — Scholarships in Natural Science are offered for competition on March 14th at Keble College and on May 2nd at Merton College and New College —At a meeting of the Hebdomadal Council held on Jan 23rd it was resolved that the hearty thanks of the University be accorded to Mr Edward Whitley B A Trinity College, for his generous and timely gift of £1000 towards the permanent endowment of the chair of pathology —The Vice-Chancellor has published a letter received from Sir William Selby Church, Bart, K C B, D M, D Sc Oxon P R C P Lond, informing him of a meeting of medical graduates held in London on Dec 20th, 1904, at which it was determined—

> That, with a view to show the strong feeling that the medical [illegible] promoting the study and teaching [illegible] the purpose of assisting in this [illegible] be the establishment and endow [illegible]

RURAL MIDWIVES' ASSOCIATION —A very well attended meeting under the auspices of the Rural Midwives *Association was held at 50 Albemarle street London* W (by kind permission of Mrs Murray) on Jan 25th Lord Edmund Talbot presided and among those present were Sir Michael Foster, Dr T Savage Dr A Bostock Hill (Warwick county council), Dr R Boxall, and Dr J Middleton Martin (medical officer of health of Gloucester) Mrs Heywood Johnstone explained that the meeting had been called to discuss the best means of carrying out the *Midwives Act in rural places and the especial difficulties in sparsely inhabited districts where even amongst the educated* classes much ignorance still remained as to the necessity for the Act and the rules laid down by the Central Midwives Board The object of this legislation might be summed up in the words ' the stamping out of puerperal fever, and it also aimed at the better nursing of the mother and child The discussion to follow would embrace the following points 1 The authorities appointed to carry out the Act 2 Inspectors 3 Inspection Besides inspecting the appliances of the nurses and their dwellings, where possible the nurses should be inspected at their work in the cottages 4 Disinfection 5 The best type of midwife for rural districts 6 Combination with nursing associations 7 Midwives acting independently 8 Financial aspects 9 Further difficulties, among which were the impossibility of a trained midwife living on her earnings and the difficulty of getting uneducated women of the servant class to assimilate theory and to be conscientious in their work Dr Boxall said that the Central Midwives Board had *expressed the opinion that a supervising* authority should make arrangements for the inspection of midwives and this would be best carried out by a local authority On this point Dr Savage representing the Warwick county council, said that they had put the [illegible] the crux of the whole question if deterioration in the work of the midwives was to be prevented Dr Boxall pointed out the supreme importance of adequate disinfection In the lying in hospital with which he was connected owing to the precautionary measures adopted out of 8837 cases treated since 1887 not one had died who had been under their care from the outset Sir Michael Foster gave it as his opinion that the best type of midwife was the woman who had practical knowledge of the class to which she was to give assistance She must be trustworthy and a person who would be accepted by the poor The *following propositions were put before the meeting —*

> 1 That a committee appointed by the county council would be the best authority to carry out the Act
>
> 2 That inspection would be best carried out by or under the supervision of, a county medical officer of health or a fully trained nurse midwife under medical supervision and not connected with local nursing associations
>
> 3 That the best form of rural midwife is a woman with an intimate and practical knowledge of the life of the working class

A vote of thanks to Mrs Murray for lending her house for the meeting and to Lord Edmund Talbot for presiding having been passed unanimously the proceedings terminated

LITERARY INTELLIGENCE —The copyright of that useful and popular handbook "Half Hours with the Microscope' by Dr Edwin Lankester, formerly published by Messrs W H Allen and Co has been acquired by Messrs C Arthur Pearson Limited, who have also purchased the companion volume by Thomas Davies, on the ' Preparation and Mounting of Microscopic Objects ' The latter has been out of print for some time but a new and cheaper edition will be published very shortly

LIVERPOOL MEDICAL INSTITUTION — At the annual meeting held on Jan 12th the following list of office bearers and members of council was adopted President Dr James Barr Vice Presidents Dr J R Logan, Dr J. Wiglesworth Dr J H Abram, and Dr George C Walker. Treasurer Mr T H Bickerton General secretary Mr F Charles Larkin Secretary of ordinary meetings Mr R W Murray Secretary of pathological meetings Dr W B Warrington Librarian Mr W Fingland Editor of the journal Dr F H Barendt Council Dr A G Gullan, Dr John Hay Dr David Morgan Mr K W Monsarrat Mr Rushton Parker, Dr F Stevenson, Mr R C Dun Dr R Thacker King Dr John Masson, Dr W McClelland Dr S J Palmer, and Mr James Taylor Auditors Dr Logan and Dr J Tawse Nisbet General committee Dr Barr Mr Larkin Mr Bickerton Dr Logan Mr Murray Dr Palmer, and Mr Rushton Parker Library committee Dr Abram Dr Hay, Mr Dun, Dr Barendt and Mr Monsarrat

DONATIONS AND BEQUESTS —The committee of the Infants Hospital has received from the trustee of the *Jessie Alice Palmer Charitable Fund the sum of £500 to* endow a cot in memory of the late Jessie Alice Palmer — Mr Alfred Stephens formerly a police officer in Hampshire, who died aged 84 years, a fortnight ago at Newport, Isle of Wight has left £2000 to the Royal County Hospital, Ryde and £1500 to the National Consumption Hospital, Ventnor —Mr James Hamilton who died on Jan 1st at Paisley, has bequeathed to the Paisley Alexandra Infirmary £300, to the Scottish National Institution for Imbecile *Children Larbert £200*, and to the Paisley Eye Infirmary, the Poor Associations Society for Treatment of Incurable Diseases and the Paisley Convalescent Home £100 each — By the will of Mrs Elizabeth Broughton Ripley £500 each have been bequeathed to the Leeds Dispensary and Leeds Infirmary and Leeds Hospital for Women and Children — Mr Edward Nixon has by will bequeathed to the Royal Hospital for Incurables and the Sussex County Hospital at Brighton £500 each —By the will of Mr John Lightfoot Newall, of Ongar Essex, estate of the gross value of *£58 083 4s 6d has been left*, of which the net personalty has been sworn at £19 333 17*s* 10*d* Subject to certain conditions and trusts, he left the residue of his son s share of his estate as to one fifth each to the Royal Northern Hospital at Liverpool the Royal Southern Hospital at Liverpool the Royal Infirmary at Liverpool, the Bluecoat Hospital at Liverpool, and the School for the Blind at Liverpool absolutely —Mr Charles Lea of Northampton has by will bequeathed £1000 to the Northern General Hospital Liverpool, for the endowment of a bed

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

ANDERSON, LOUISA GARRETT, M.D., B.S. Lond., has been appointed Assistant Out-patient Surgeon to the New Hospital for Women, London.

BIRMINGHAM, C. L., M.D. R.U.I., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Westport District of the county of Mayo.

BORROWMAN, PHILIP, M.D. Edin., has been appointed a Medical Referee under the Workmen's Compensation Acts, 1897 and 1900, and to act for the Central District of the Sheriffdom of Perth.

BROWN, A. CARNARVON, M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Casualty Officer and House Surgeon to the North-Eastern Hospital for Children, Hackney-road.

CRAIG, GEORGE, M.B. Edin., has been appointed Public Vaccinator for the District of Ohinemuri.

CUNNING, JOSEPH, M.B., B.S. Melb., F.R.C.S. Eng., has been appointed Assistant Surgeon to the Royal Free Hospital, London.

FENNELL, CHARLES H., M.A., M.D. Oxon., M.R.C.P. Lond., has been appointed Senior Assistant Medical Officer to the East Sussex County Asylum, Hellingly.

FERGUSON, WILLIAM, M.D., has been appointed a Medical Referee under the Workmen's Compensation Acts, 1897 and 1900, and to act for the District of Banff, in the Sheriffdom of Aberdeen, Kincardine, and Banff.

FFROST, A. F., M.B., Ch.B. Melb., has been appointed Official Visitor to the Reception House at Townsville, Melbourne, Australia.

FRASER, JOHN H. P., B.A., M.B., B.C. Cantab., M.R.C.S., L.R.C.P. Lond., has been appointed Assistant Physician to the Royal South Hants and Southampton Hospital.

GRIFFITHS, T. R., L.R.C.P. Edin., L.R.C.S. Edin., L.F.P S. Glasg., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Kidwelly District of the county of Carmarthen.

HAMILTON, C. W., M.D. Dub., has been appointed Honorary Laryngologist to the Consumptive Sanatorium, Belair, South Australia.

HAMILTON, T. K., M.D. Dub., F.R.C.S. Irel., has been appointed Honorary Laryngologist to the Consumptive Sanatorium, Belair, South Australia.

HOPKINS, G. H., F.R.C.S. Eng., has been been appointed Honorary *Visiting Surgeon, Brisbane Hospital, Queensland, Australia.*

JACKMAN, JAMES JOSEPH HAYES, F.R.C.S.I., has been appointed a Medical Referee under the Workmen's Compensation Acts, 1897 and 1900, and to act for the City and County of Waterford.

LENNANE, G. Q., F.R.C.S., L.R.C.P., has been appointed Clinical Assistant to the Chelsea Hospital for Women.

MACLENNAN, ALEX., M.B., C.M. Glasg., has been appointed Dispensary Surgeon, Western Infirmary, Glasgow.

MOORE, THOMAS CHARLES, M.B., Ch.B. Dub., has been appointed Public Vaccinator for the District of Napier, New Zealand.

ORR, A. W., M.D. Dub., L.K.Q.C.P., has been appointed Honorary Assistant Surgeon to the Eye, Ear, Nose, and Throat Department, Brisbane Hospital, Queensland, Australia.

PARSONS, J. HERBERT, B.S., D.Sc. Lond., F.R.C.S. Eng., has been appointed Assistant Surgeon to the Royal London (Moorfields) Ophthalmic Hospital.

REISSMANN, CHARLES HENRY, M.D. Cantab., M.R.C.P. Lond., has been appointed Honorary Assistant Physician to the Consumptive Department, Adelaide Hospital, South Australia.

RUSSELL, HERBERT HENRY ERNEST, L.R.C.S., L.R.C.P. Edin., L.F.P.S. Glasg., has been appointed Honorary Assistant Bacteriologist, Adelaide Hospital, South Australia.

RYAN, J. F., L.R.C.P. Edin., L.R.C.S. Edin., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Loughrea District of the County of Galway.

SHONE, WILLIAM VERNON, M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Public Vaccinator for the District of Christchurch, New Zealand.

STURROCK, PETER STURROCK, M.B., B.C. Cantab., has been appointed a Medical Referee under the Workmen's Compensation Acts, 1897 and 1900, and to act for the Dunfermline and Kinross District in the Sheriffdom of Fife and Kinross.

THURSFIELD, HUGH, M.D., M.R.C.P. Lond., has been appointed Assistant Physician to the Hospital for Sick Children, Great Ormond-street.

WALKER, EDWARD, M.D. Edin., M.R.C.S., has been appointed Honorary Physician to the Huddersfield Infirmary.

WHITE, GEORGE VINCENT, M.B., B.S. Melb., has been appointed Acting Health Officer at Thursday Island, Queensland, Australia, Surgeon of the Prison at that place, Medical Superintendent of the Quarantine Station at Friday Island, and Medical Officer for lepers detained in the lazaret at Friday Island, *pro tem*

Vacancies.

BRISTOL ROYAL INFIRMARY.—Resident Obstetric Officer. Salary £75 per annum, with board, lodging, and washing.

BUXTON, DERBYSHIRE, DEVONSHIRE HOSPITAL.—Assistant House Surgeon. Salary £70 per annum, with apartments, board, and laundry.

CHELSEA HOSPITAL FOR WOMEN, Fulham-road, S.W.—Clinical Assistant.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria-park, E.—Physician to Out-patients.

COUNTY OF LONDON, LONDON COUNTY COUNCIL.—Medical Officer to employees in District No. 4.

EDINBURGH, CRAIG-LEITH POORHOUSE AND HOSPITAL.—Resident Medical Officer. Salary at rate of £100 per annum, with board and apartments.

EGYPTIAN GOVERNMENT (MINISTRY OF PUBLIC INSTRUCTION).—Professor of Pathology and Bacteriology at the School of Medicine, Cairo. Salary £800 per annum.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark, S.E.—Physician to Out-patients.

GROVE HALL ASYLUM, Bow, London, E—Assistant Medical Officer. Salary at rate of £150 per annum, with board, apartments, attend- [illegible]

[illegible] AND EYE HOSPITAL.—Assistant House Surgeon for six months [illegible]

HOSPITAL FOR SICK CHILDREN, Great Ormond street, London, W.C.—House Physician, unmarried, for six months. Salary £20, with board and residence.

[illegible] n, unmarried. [illegible] of Anatomy, [illegible] sistant Surgeon [illegible]

MEDICAL DEPARTMENT OF THE NAVY, Victoria-street, S W.—Three Dental Surgeons Salary £1 per diem and (when necessary) travelling expenses

NAPSBURY ASYLUM, near St Albans, Herts —First Assistant Medical Officer, salary £300 per annum; Second Assistant Medical Officer, salary £220 per annum, and Third Assistant Medical Officer, [illegible] —House [illegible] tor and [illegible] asualty [illegible] attendance

SHEFFIELD ROYAL HOSPITAL.—Assistant House Physician, unmarried. Salary £50 per annum, with board and lodging

SOCIETY OF APOTHECARIES OF LONDON —Gillson Scholarship in Pathology. Value £90

TEIGNMOUTH HOSPITAL, S Devon —House Surgeon Salary £70 a year, with board, lodging, and washing.

WELLS, SOMERSET AND BATH LUNATIC ASYLUM —Medical Superintendent Salary £600 per annum with house and allowances

WESTMINSTER GENERAL DISPENSARY.—Honorary Surgeon.

THE [illegible]

THE Chief Inspector of Factories gives notice of vacancies as Certifying Surgeon under the Factory and Workshop Act at Chertsey in the County of Surrey, at Knottingley in the County of York, at Pangbourne and Whitchurch in the Counties of Berks and Oxford, and at Littleport in the County of Cambridge.

Births, Marriages, and Deaths.

BIRTHS.

LAY —*On Jan 29th, at Peasenhall, Suffolk, the wife of Charles E Lay*, L R C P, L R C S, L M, of a daughter.

WHEATON —On Jan. 30th, at 10, Rastell avenue, Streatham hill, S W, the wife of S Walton Wheaton, M D Lond, M R C P, D P H, of twin daughters

MARRIAGES.

BEATTON—CALLAS —On the 25th Jan, 1905, at Greyfriars Church, Reading, by the Rev S H Soole, Vicar, assisted by the Rev Bathurst Soole, Gilbert T Beatton, Esq, M D, The Cliffe, Bradford, Yorks, to Ada Elizabeth (Dolly), youngest daughter of Alfred Callas, Esq, of Lexden, Bath road, Reading At home, The [illegible]

SPRIGGE [illegible]

DEATHS.

BOTHAMLEY.—On Jan 23rd, at 14, Balham hill, S.W., aged 51, William Parkinson Bothamley, M R C.S, L.S A.

LING —On Feb 1st, Maurice Edward Ling, M D, of Harley House [illegible]

[illegible] Bognor, Louie, wife of John Young, [illegible] *at Putney Vale Cemetery 1 30 on* [illegible]

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

SWEDENBORG'S ACCOUNT OF THE VERMIFORM APPENDIX.

A CORRESPONDENT writes to us as follows "As diseases of the appendix are occupying a good deal of attention in the medical and scientific world it might be of interest to some of your readers to hear what Swedenborg wrote about this in his 'Animal Kingdom,' published *in 1744 Swedenborg says that the appendix opens its* pores and expands its cavity synchronously with the cæcum and pours into the cæcum and colon a liquid adapted for lubricating the wavy folds of the colon and particularly for macerating the fæces. In support of these views he quotes various anatomical authorities in a very long footnote, of which the following is part —

> 'For if the intestines do not pour forth fluid at all, but only absorb it, then in this case, without a fresh spring, they would soon dry up, and the food, which in these intestines is a heavy, tenacious, and fetid mass, would collect and harden, to the entire destruction of life To avoid these consequences, is apparently the purpose of the vermiform appendix, which continually pours a humor, *adapted for performing this last office into the beginning* of the large intestines The structure of the appendix, and many experimental observations made upon it, bear out this view. "Its internal coat," says Winslow, "is plentifully furnished with follicles, and it is likewise reticular, the meshes being the glandular lacunæ, which continually discharge a fluid into its cavity' And Wepfer says: "In the appendix I found a white, turbid mucus when this was wiped off, the whole of the internal surface appeared to be covered with little foramina, from which, on squeezing the appendix, a white, turbid liquid issued, and it was plain that the whole appendix was *of a tubular composition" Morgagni also holds the* same opinion, because, when the cæcum and ileum were distended with flatus, no air was observed in the appendix, nor (according to an observation o Zambeccari), when the appendix was cut off, were any fæces found to pass into the cavity of the abdomen, and further, because the appendix is inserted in the end of the cæcum, or the beginning of the colon, and in two cases, a very remarkable [illegible] impossible for [illegible] (Advers [illegible] vity, even [illegible] tself is so [illegible] furnished with numerous glands, [illegible] comparatively erect, and not flat [illegible] h consequently are emissary or excretory Similar little appendices or cæca, also called vasa variosa, are found in all worms and insects being inserted into both the colon and the duodenum; plainly for a similar purpose From the meeting of the ligaments on the appendix, it may be inferred, that its excretion is more abundant during the full action of the colon And for this reason, animals which live on hard [illegible] have several [illegible] ended with a [illegible] s Moreover, [illegible] found in the colon'

In another long footnote Swedenborg discusses the nature and origin of this fluid which issues from the appendix and argues that it is 'the superfluous lymph of the peritoneum' He remarks also that in the body the 'recrementitious humors' always perform some use before they are thrown out

HOLT OCKLEY NURSING SYSTEM.

To the Editors of THE LANCET.

SIRS,—Will any of your readers with experience inform me as to successes or failures of the above system, and in failures the reasons of want of success? Any letters addressed to me as below will be gratefully acknowledged and considered absolutely confidential

I am, Sirs, yours faithfully,
H. T. WHITLING, M.B Durh

Husbands Bosworth, Rugby, Feb 1st, 1905

PARIS SEWAGE.

IN an editorial article the *Engineer* of Jan. 27th states that the Prefect of the Seine has just brought out a scheme for the creation of a double system of septic tanks and contact beds, this being the first official acknowledgment that *the sewage farms have not done all* that was expected of them. Various difficulties have, however, been encountered in the working of the Paris sewage farms and have been [illegible] when the [illegible] more [illegible] abandonment of the *Achères farms because* the [illegible] who had leased them found that the land was so swamped with sewage that cultivation was unremunerative. The Pierrelaye and Méry farms have also given trouble and it is said that the main cause of the failure of all the farms is that at least twice as much sewage had been diverted on to them as they were intended to receive. Heavy damages are also being claimed by leaseholders on the sewage farms and by others who have suffered from the indiscriminate discharge of sewage. The Paris municipal council is therefore desirous of trying other means of sewage disposal and last year delegated a number of engineers to visit some of the bacterial installations in England and to report upon this system. The first bacterial installation in France has been laid down at Lille and a very favourable report upon it has been made.

A HOME FOR THE WEIR MITCHELL TREATMENT.

To the Editors of THE LANCET.

SIRS,—Will any of your readers be so good as to inform me of the address of an institute where a patient of limited means could be admitted to undergo the "Weir Mitchell" treatment? I do not think that she could afford more than about 10*s*. a week.

I am, Sirs, yours faithfully,
Ravenhurst, Talbot-road, Wembley, Feb. 1st, 1905. H. W. ARMIT.

A MODIFIED FORM OF EARTH CLOSET.

WE have received from Mr. R. J. H. Parkinson of Mablethorpe, Lincolnshire, an illustrated description of a form of closet which he has devised—namely, a modification of the "type in which a deodoriser such as earth or other substance may be employed." Its essential feature is that fæces and urine, although simultaneously received in the same vessel or pan, are immediately separated from one another, the solid matter being retained on the surface of a layer of straw packed in the pan, while the fluid portion drains away through a hole in the bottom of the pan into a sewer, cesspool, or other container. The pan is intended to stand on the ground underneath the seat of the closet and below the level of the floor; for the purpose of being emptied it is easily removed through a small door in the back wall below the floor level.

THE CASE OF DR. A. D. GRIFFITHS.

To the Editors of THE LANCET.

SIRS,—Will you kindly announce the following additions to the amount promised towards the Arthur Griffiths testimonial fund?

	£	*s.*	*d.*
Amount already acknowledged	22	15	6
Sir R. Douglas Powell ...	2	2	0
Mr. Howell Rees (further subscription)	0	16	0
Dr. M. H. Greener	1	1	0
Mr. W. Edmund Thomas	2	2	0
Dr. B. W. Broad	1	1	0
Mr. Percy W. Griffiths ...	1	1	0

I am, Sirs, yours faithfully,
A. P. FIDDIAN, Treasurer.
23, The Walk, Cardiff, Jan. 31st, 1905.

THE "GLASEPTIC" NEBULISER.

THE important advantage of this neat little nebuliser is that it is constructed entirely of glass so that no oxidation or corrosion can happen to it. In addition, it is easily cleansed and, if need be, rendered aseptic. It is a very effective "nebuliser" and it works efficiently even with a few drops of liquid, and it answers equally well whether the agent is viscid or mobile. Thus it is adapted to the "atomising" of solutions of any density, concentrated saline solutions, oily fluids, or ethereal or spirituous menstrua. The glass portion—i.e., that portion apart from the bellows—measures only three and a half inches high by one and three-quarter inches in diameter, so that it is easily accommodated in the pocket. The apparatus may be corked and the active agent in it preserved. The "glaseptic" nebuliser can be obtained from Messrs. Parke, Davis, and Co., of 111, Queen Victoria-street, London, E.C.

ASEPTIC FURNITURE.

To the Editors of THE LANCET.

SIRS,—We notice on page 97 of THE LANCET of Jan. 14th an illustration of an aseptic table made by Messrs. Allen and Hanburys. Not only is this table an almost exact copy of our university table, introduced five years ago, but their illustration is evidently inspired by our own, which has been freely distributed for the last four years. We believe we were the first makers to use phosphor bronze in the construction of aseptic furniture, making some specimens for University College Hospital early in 1902, which we afterwards submitted to the staff of the New St. Mary's Hospital, Manchester. Our samples being accepted we fitted up the principal operation theatre of that institution entirely with phosphor bronze furniture.

We are, Sirs, yours faithfully,
MAYER AND MELTZER.
Great Portland-street, London, W., Jan. 27th, 1905.

POCKET ALBUMIN TEST CASE.

THIS is a convenient and handy application of the salicyl-sulphonic acid test for albumin in the urine. The apparatus consists of a small glass pipette provided with a constriction situated about an inch from the point. A rubber cap is attached to the top of the pipette by means of which a small volume of urine may be introduced into it. Before this is done a tablet of salicyl-sulphonic acid is dropped into the upper end of the pipette and will rest upon the constricted portion of the tube. The tablet serves to divide the pipette, and hence the volume of urine, into two portions. As the salicyl-sulphonic acid dissolves a stream of the solution descends into the lower volume of urine when, if albumin is present, there is an immediate precipitate. The upper portion remains clear since no reagent reaches it and hence a comparison is easily made. In the event of a precipitate forming the fluid is boiled, when if albumin is present the fluid remains turbid. The entire apparatus in a polished metal case is only three and a half inches in length, so that it may be conveniently carried in the waistcoat pocket in the same way as a clinical thermometer. Messrs. Allen and Hanburys of 37, Lombard-street, London, E.C., are the makers.

WHOLESOME LITERATURE.

ON Feb. 14th a new paper for boys, and especially for those of our elementary schools, will be published by the Religious Tract Society, with a view of counteracting the effects of the literary garbage still so largely circulated amongst lads. It will be conducted by Mr. G. A. Hutchison who projected and has edited from the first, now over 26 years ago, the well-known *Boy's Own Paper*, will cost only 1*d*. per number, and will bear the name of *Every Boy's Monthly*.

◆

Candidate.—The books mentioned by our correspondent will amply suffice but we advise him to pay most attention to Osler's Medicine in the list of medical books. As to the history of medicine, a valuable compendium is "Medical History from the Earliest Times," by Dr. E. T. Withington, published by the Scientific Press.

Mr. James S. Elder.—The composition of the preparation was thus given by Dr. Robert Hutchison in THE LANCET of Nov. 28th, 1903, p. 1493: atropine, cocaine, hyponitrous acid, and various balsamic extracts, administered by means of an "aeriser."

I.M.S.—Our correspondent will find in THE LANCET of Sept. 3rd, 1904, a list of books recommended for the higher qualifications which will, doubtless, serve his purpose.

M.D.—We do not think that there is any objection to the course proposed provided that the card is only sent to patients on the books.

J. M.—Our correspondent will find full details in THE LANCET of Sept. 5th, 1903, p. 650.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (6th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. EDITORIAL NOTICES.

IT is most important [illegible] Editorial business of [illegible] *exclusively* "TO THE [illegible] gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. II. of 1904, which was completed with the issue of Dec. 31st, and the Title-page to the Volume, were given in THE LANCET of Jan. 7th.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1904 are now ready. Bound in cloth, gilt lettered, price 18*s.* carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.				TO THE COLONIES AND ABROAD.			
One Year	£1	12	6	One Year	£1	14	8
Six Months	0	16	3	Six Months	0	17	4
Three Months	0	8	2	Three Months	0	8	8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 31, Rue Bapts, Asnières, Paris.

dusky and the respirations were quicker and shorter. It was evident, in fact, that the pus was all the while trickling into, and filling, the lung. Rapidly a piece of the eighth rib was removed in the anterior axillary line, the healthy pleura was opened, and the diaphragm was exposed. This was cut through with a knife, when at once came a rush of thin foul pus, projecting a foot from the surface of t[illegible] against the side with [illegible] irrigated. Then two [illegible] gauze were inserted [illegible] and to compress the diaphragm against the ribs. The breathing quieted and the colour improved at once. The collection was above the liver, to the right of the suspensory ligament, and was bounded below by the stomach and colon and amounted to close on two pints. The pleura was free. Looking in through the large opening, for it was near two inches long, one could see the diaphragm and the liver. Desperate as was the condition the outlook was still [illegible]able, for there was no hepatic infection, the [illegible] peritoneum showed no irritation, and there was n[illegible]monia.

On Monday, two days later, I saw the girl again. All urgent symptoms had subsided and there was a free escape of thin pus. For a few hours in the morning of this day the foul expectoration had returned; this was due to the gauze blocking the tube. The gauze being loose I removed both tubes and re-inserted one covered again with gauze. It was interesting to notice that in the period of about 56 hours the pleural cavity had been fully sealed. Rapid progress towards recovery followed. I noticed that the appendix wound was quite insignificant on this the tenth day from the first operation.

Before adding some general remarks it may be asked whether [illegible] not have been delayed in view [illegible] opinion that subphrenic abscesse[illegible] well. In this case the conditio[illegible] thin and abundant, and delay would, I believe, have been fatal. Personally, I do not think it wise to leave any case to itself where the pus is being expectorated. In empyema and in hepatic abscess I [illegible]nd much loss of strength result. [illegible] symptoms following free in[illegible]peration. Going back for a moment it must be noted that the first operation was made fairly early in the case—the third day or beginning of the fourth. If we were in a position to say that no danger need be introduced by operation then early interference should be our rule when symptoms do not spontaneously subside—i.e., without the use of opium. I operated eight years ago on a case within 20 hours of onset because pain was not relieved. I found an abscess with a perforation at the root of the appendix. The appendix was removed, the cæcum was closed, and without any drain the patient, [illegible].

Since [illegible]ry mopping, a[illegible] greatly improved. In borderland cases operated upon on the fifth or sixth day I am certain that flushing will turn the scale to a fatal issue. Some of my earlier cases would probably have recovered had this method been omitted. In very early cases —i.e., those operated upon in from 24 to 36 hours—recovery will generally follow with any method, provided all septic material existing at the time be removed. Even incomplete removal of pus without drainage may succeed, as I will show you another time. I mention the fact here to impress the importance and the safety of early operation.

My working rule is a simple one and it is this. After the initial pain has been relieved by a full sedative the persistence of any one sign of extension should cause anxiety and determine operation on the second, third, or fourth day, or in the worst cases earlier. A patient who required opium at the end of 48 hours should, as a rule, not have the drug but an operation. Some leading sign will certainly be present. There will be a continuously high temperature, associated with signs of general irritation, as in the case related here, or continued pain, or abdominal distension unrelieved by remedies, or an increasing swelling, [illegible]ution. Or there may be sickness. Many have said to me, "He is better, because there has been no sickness for four days." My reply always to that statement is this, How do you know when you have given nothing by the mouth? In such a case I gave a man a bowl of milk at 7 o'clock and he kept it down and at 10 o'clock was no worse. I ordered another, convinced that he had a stomach full of foul material. In six hours he vomited a basinful of foul brown fluid and all were convinced of the necessity of operation but it was too late. Absence of vomiting is of little value when feeding is withheld. The guides in our case to-day were three: a stage of moderate pain preceding the onset, a continuously high temperature with general irritation, and an increasing swelling.

Before leaving this point let me urge upon you the importance of a few conclusions I have laid down for my guidance and have acted upon for a good many years. First, never to give opium after the initial dose required to relieve pain. More harm is done by prescribing opium every four hours than anything. If the pain continue severe after 24 hours operation will almost invariably be required. Secondly, when in any doubt at all advise operation. [illegible]ay remember you ought, if the case [illegible] to handle the swellings fairly freely and all symptoms should be subsiding. It is a dangerous day and if symptoms are progessing operation is the best rule.

Next let us discuss the operation selected in this case. The abdomen was opened by separating the fibres of the abdominal muscles. Abundance of room was obtained in this way. It is the best of all methods and especially in foul abscess [illegible] required. [illegible] and there is [illegible] woman, aged 45 years, where the abscess was chiefly above the iliac crest and where abundance of room could be obtained by separation of muscular fibres. But for most of you this will not give sufficient room. For a beginner I do not recommend this plan in acute conditions where the appendix must be removed. For a localised abscess where the appendix need not be removed, say on the eighth or tenth day, it answers admirably and should be selected in preference to division of the muscle.

There is another route which I strongly recommend you to learn and to practise on the cadaver and which I adopt in all acute cases where the abscess is high up or low down or lies nearer the median line than usual; or again in relapsing cases, where extensive adhesions are expected and the appendix lies probably in the pelvis or near the kidney. I must defer the details to another lecture, but may say here that it consists in cutting through the rectus sheath, dissecting the outer border of the muscle inwards, isolating and preserving the nerves, and then opening the posterior layer of the sheath. The region from the pelvis to the loin can be commanded, no muscle is divided, and no nerve need be destroyed. I owe my knowledge of this [illegible] one of Germany's best surgeons, [illegible] and consider you should learn [illegible] as you do that of celotomy, for you must be prepared to operate, and I hope to show you [illegible] can in most cases be traced upwards from the appendix. In this instance, though no pus was found about the colon, there [illegible] of the bowel. The [illegible] frequently to the r[illegible]r and presents below the ribs, pushing down the liver. Its exact situation is usually determined by an exploring needle inserted in the mid-axillary line. In this case the first punctures were made behind because of the pulmonary signs and a little time was lost.

On account of the coughing and mental excitement no adequate examination could be made before the administration of the chloroform and as the cyanosis was deepening it was thought better to explore freely at once. Pus was found on puncturing the eighth space and a piece of the eighth rib was removed. The danger of pleural infection will occur to you and it must be considered a serious one. The patient's condition at this moment demanded the greatest speed, for the lung was clearly filling with pus, otherwise the diaphragmatic pleura could have been sutured to that of the costal pleura and the cavity shut off. The plan of direct incision was adopted and the diaphragm held against the ribs. This plan has answered in my hands on several occasions and provided a gauze-covered rubber tube be introduced which will plug the opening and keep the parts in contact the plan will be found a good one. If time permits, as in the last two operations in Job ward, the pleura can be sutured.

Can an abscess in this situation be opened below the ribs in front? Does it project sufficiently far down to be accessible? In this instance an examination of the cavity after incision showed that the abscess could have been evacuated from the front. I have operated from the front but so far prefer the transthoracic route. The subject of subphrenic abscess requires a full investigation and I commend it to any of you in want of a subject for a thesis.

ON DUODENAL ULCER; WITH NOTES OF 52 OPERATIONS.

By B. G. A. MOYNIHAN, M.S. LOND., F.R.C.S. ENG.,
SENIOR ASSISTANT SURGEON TO THE LEEDS GENERAL INFIRMARY; CONSULTING SURGEON TO THE SKIPTON HOSPITAL AND TO THE MIRFIELD MEMORIAL HOSPITAL.

IN THE LANCET of Dec. 14th, [illegible] subject of duodenal ulcer and r[illegible] ulcer and two cases of perforating ulcer upon which I had operated. During the last three years my experience of this condition has been considerable, and I propose in this paper to give a brief record of the cases I have seen and to discuss, at greater length than was possible before, the symptoms and the surgical treatment.

From January, 1900, the date of my first operation, to September, 1904, I had operated upon 51 cases. There were seven cases of perforating duodenal ulcer with five recoveries, 22 operations for duodenal ulcer associated with gastric ulcer with one death, and 23 operations for duodenal ulcer alone with one death. The proportion which [illegible] operations bear to the total number of my operation[illegible] simple diseases of the stomach may be gathered fron[illegible] following complete summary of my experience:—

	Cases.	Deaths.
Gastro enterostomy for gastric and duodenal ulcer (including cases of hæmorrhage) ...	162	14
Perforating ulcer of the stomach and duodenum	20	8
Hour glass stomach	19	3
Pyloroplasty	3	0
Finney's operation (gastro duodenostomy) ...	2	0
Gastroplication	1	0
Excision of an ulcer for hæmorrhage	1	1

The relative frequency of duodenal ulcer to gastric ulcer has been, therefore, greater in my experience than in many of the statistics which have been published by others. But any discrepancy in this particular is easily accounted for by the fact that the statistics which are quoted in the text-books of medicine are based exclusively upon post-mortem examinations, whereas my investigations have been confined to the living.

Almost all writers remark upon the rarity of ulcer of the duodenum. There can be no doubt, however, that it is by no means so infrequent as is supposed. A series of over 50 operations occurring in the practice of one surgeon disposes entirely of any question as to the great rarity of the disease. The observation of the condition of the gall-bladder and stomach by the surgeon during life has greatly altered our knowledge of the diseases which affect these organs. I submit that duodenal ulcer is far more common than has been formerly believed and that the association of duodenal ulcer with gastric ulcer is frequent. During the last few years a not inconsiderable number of cases have been reported in the medical journals as having been treated surgically on account of perforation, duodenal stenosis, or hæmorrhage. Side by side with the statement as to the infrequency of duodenal ulcer which is contained in most of the text-books of medicine is the remark that the condition is one which is extremely difficult to diagnose. The one observation may explain the other; as a fact, neither statement is accurate.

The symptoms of duodenal ulcer in many cases are perfectly characteristic and admit of an unhesitating diagnosis. I am compelled to dissent very confidently from the statement so often repeated that it is impossible to distinguish between an ulcer of the stomach and an ulcer of the duodenum. Even in those cases in which both gastric and duodenal ulcers are present, when the difficulty of diagnosis might be expected to be at its highest, a careful scrutiny of the history will generally allow a discrimination to be made between the symptoms due to the one and those due to the other condition. I do not pretend to say that in all cases the diagnosis is easy; on the contrary, in some cases it is impossible, because gastric ulcer and gall-bladder disease may both be complications in the same case. In many cases, however, a diagnosis is possible and in some is unmistakeable.

Position of the ulcer.—Duodenal ulcers are generally situated in the first portion of the duodenum. Collin found in a series of 262 cases that 242 were placed in the first portion, 14 in the second, three in the third, and three in the fourth. Perry and Shaw found that in 149 cases 123 were situated in the first portion, 16 in the second, and two in the third and fourth; in eight cases the ulcers were scattered. Oppenheimer states that in 81 cases 69 were situated in the first part, eight in the second, and four in the third and fourth. Ulcers in the first portion of the duodenum, then, are at least ten times more frequent than in the second. Schwartz has recorded one case of perforation of an ulcer on a level with, or a little below, the ampulla of Vater. Bile [illegible] the opening and was found free in the [illegible]. In my series of cases all the ulcers which perforated were in the first portion of the duodenum; of the chronic ulcers 43 were in the first portion and one was in the second portion.

The ulcers may be multiple though they are usually solitary. If there are many ulcers they are usually crowded together in the first portion of the duodenum, but ulcers in the first portion associated with ulcers in the second or third portion are recorded by Clark, Schwartz, and Dudensing. In one of my cases an ulcer which was on the anterior wall had perforated; immediately opposed to it on the posterior wall was an ulcer of the same size and shape.

The association of gastric and duodenal ulcers had [illegible] or no attention before I pointed out its fre[illegible]per read before the Clinical Society of London [illegible]y series of 44 cases there were 22 in which a gastric ulcer or ulcers were also present. W. J. Mayo found gastric ulcer present in over 50 per cent. of his cases. The reason for this association is not difficult to understand. In peptic ulcer of the stomach there is a marked increase in the amount of free hydrochloric acid; when the acid stomach contents escape into the duodenum they cause a peptic ulcer in that part of the wall with which they first come in contact, destroying its mucosa by digestion. The sequence of events then is gastric ulcer, hyperchlorhydria, duodenal ulcer. The shyness of the duodenum to the contact of acids is illustrated in the work of Pawlow.

One important point that has been established by the work of the surgeon upon the stomach is the frequency of multiple ulcers in the stomach or in the duodenum, or in both. In the statistics gathered together in the various text-books of medicine it is shown that gastric ulcer is usually solitary. The reverse is the fact. Gastric ulcer is rarely solitary, there are often more ulcers than one in the stomach, and, as I have said, duodenal ulcer is associated with gastric ulcer in approximately one-half of the cases.

Age.—Duodenal ulcer may occur at any age. Oppenheimer has collected the records of 15 cases of melæna neonatorum resulting from ulcer of the duodenum. Chvostek, in a series of 87 post-mortem examinations in children under ten years of age, found ulceration of the duodenum in five; three of the children were aged three hours, four days, and seven weeks respectively. T. D. Lister observed a duodenal ulcer in a child three days old and Spiegelberg one in a child four days old. Landau has suggested that these ulcers are due to emboli carried away from thrombi in the umbilicus. Ulcer of the duodenum in the newly born is also recorded by Henoch, Zerschwitz, and Dusser. Collin in 297 cases of duodenal ulcer found that they occurred as follows:—

Under 10 years of age	42 cases.
Between 10 years and 20 years	24 "
" 30 " 40 "	52 "
" 40 " 50 "	46 "
" 50 " 60 "	41 "
" 60 " 80 "	28 "
" 80 " 95 "	3 "

In my own cases the ages of the patients in whom perforation occurred were 44, 25, 17, 17, 25, 22, and 40 years. In the remaining cases the ages ranged from 19 to 61 years.

Sex.—Duodenal ulcer is usually said to be very much more common in the male than in the female. The ratio given by various writers is as follows: Weir, 6 to 1; Collin, 5 to 1; Cullen, 5·6 to 1; Fenwick, 4 to 1; Perry and Shaw (excluding ulcers due to burns), 6 to 1; and Mayo and Graham, 2·5 to 1. In my 51 cases there were 32 males and 19 females.

Symptoms.—The symptoms of duodenal ulcer are pain, hæmatemesis, and melæna. In a certain number of cases (estimated by Morot at 20 per cent.) the ulcer remains latent for long periods and its presence is only revealed by perforation or the occurrence of hæmorrhage. In 151 cases collected by Perry and Shaw in which duodenal ulceration was found post mortem there were 91 in which no history of antecedent symptoms could be obtained.

Pain is sometimes slight and does not amount in the earlier stages of the disease to anything more than a vague uneasiness in the epigastrium. The pain is described as being of a burning character at the first and it is felt chiefly in the middle line or along the right costal margin. By degrees the pain becomes more and more severe and may, in certain cases, be so intense as to render the patient entirely unfitted for work. Many patients say that the pain is cramp-like in character and that they receive the impression of something gathering force by slow but inevitable degrees. When severe the pain is always worse to the right of the middle line. In some cases, especially in those where adhesions to the under surface of the liver or to the gall-bladder are subsequently found, there may be a complaint of pain radiating upwards to the right breast. A pain which passes round the chest to the back is sometimes felt.

There can be no question that the time of the onset of pain after food affords valuable information. If the pain does not come on for from two to four hours after a meal then I feel sure that we are entitled to say that the ulcer is either at the pylorus or very near to it. In such circumstances the patient will often complain of what I have been accustomed to call "hunger pain." This pain begins at about 11 or 12 o'clock in the morning if breakfast has been taken at 8 or 9 A.M.; it begins, that is to say, at a time when a patient is beginning ordinarily to feel that another meal is due. In not a few cases the sufferers have discovered for themselves that the taking of food as soon as the "hunger pain" begins will relieve it. A biscuit and a drink of water or of milk will give almost instant relief. As soon, however, as this is digested the pain slowly returns, to be again dispelled by the taking of food. One hears, not rarely, that the patient feels as though he was assured of comfort "if the stomach is working." For this reason a heavy meal will be eaten in order that the onset of pain may be postponed, or food of a particularly "indigestible" character will be taken in order that the stomach may be kept longer at work digesting it. Three of the patients upon whom I have operated have told me that a glass of wine or a little brandy and water has eased the pain for perhaps half an hour. A copious draught of water is not so effective in the removal of the pain as a little solid food. Many of the patients, therefore, do not restrict their diet, at least in the early stages of the disease. On the contrary, they not infrequently eat more than they have been accustomed to and are inclined to boast of their ability to "eat anything." During this period they do not, therefore, lose weight; indeed, they are perhaps sleek and well-conditioned. It is owing to the hyperacidity of the gastric juice that they are able to digest a heavier meal than they have formerly been accustomed to take.

The cause of the pain in duodenal ulcer has not been determined; it may be different in different cases or in the same case at different periods. Among the more likely causes are the irritation of the open ulcer by the acid gastric contents, the degree of acidity and, therefore, of irritation increasing as digestion proc [illegible] the stomach or duodenum [illegible] of a localised peritonitis. [illegible] drinking of a little sherry or brandy and water is due, it is suggested, either to the closure of the pylorus, caused by the irritant action of the fluid, or to the dilution of the excess of free hydrochloric acid. The taking of a biscuit or a little solid food certainly gives the hydrochloric acid which is in excess "something to do" and it keeps the stomach at work and postpones the propulsion of the stomach contents through the pylorus for a brief period. In some cases the pain is of a colicky nature and is due almost certainly to a spasm of the pylorus or pyloric antrum. I have seen a patient suffering from an attack of pain which to me (and to him—he was a medical man) was indistinguishable from hepatic colic. In later stages the pain alters somewhat in character. It becomes more severe, more continuous, and less capable of being relieved by food or drugs. It occasionally happens that the taking of solid food causes a great increase of the pain and that the patient for this reason may curtail his diet, live only on milk and other fluids, and thereby determine a marked loss of weight.

In some cases it has been possible to diagnose beforehand, with reasonable certainty, the presence of both gastric and duodenal ulcers in the same patient. The time of the onset of pain is then of great importance. When pain begins very shortly after food is taken, then gradually becomes easier, and again undergoes marked exacerbation, it has been taken as showing that both forms of ulcer are present, that the early pain was due to the irritation of the gastric ulcer, the period of repose to the alteration in the physical characters (bulk, temperature, &c.) of the food, and the exacerbation of pain due to the irritation of the duodenal ulcer.

Hæmatemesis and melæna.—These may be present together or either may be present in the absence of the other. It is probable that the passage of blood by the bowel would be found to be more frequent than my statistics show if all cases were carefully examined in the manner suggested by Boas in order to discover traces of blood in the fæces when a quantity not visible to the naked eye is present. Small quantities of blood discharged in vomit are more likely to attract attention than moderate or even large quantities passed in the motions. The disproportion between the frequency [illegible] therefore, not [illegible] the kind now t [illegible] cases presenting symptoms hæmatemesis was present in 14 and melæna was present in nine.

Nothnagel considers that severe hæmorrhage—that is, hæmorrhage which is not so insignificant as to pass undiscovered—occurs in one-third of the cases. Fenwick estimates the frequency of hæmorrhage in acute cases at 26 per cent. and in chronic cases at 40 per cent. Oppenheimer found blood in the stools of 50 per cent. of his patients. In my series of 23 cases of duodenal ulcer alone hæmatemesis and melæna were observed in four cases, hæmatemesis alone in three cases, and melæna alone in two cases. In the 21 cases of duodenal ulcer associated with gastric ulcer, hæmatemesis and melæna were present in six cases, hæmatemesis alone in four cases, and melæna alone in three cases.

The amount of blood lost is sometimes considerable. Faintness has occurred in two of my patients, and one patient, in whom the hæmorrhage was so severe that I operated to check it, fainted as he was lifted on to the operation table. In such cases the intestine may be found to be full of blood when the abdomen is opened; the colon I have seen fully distended with blood which showed through the walls a vivid deep-blue colour. Hæmorrhage from a duodenal ulcer is certainly more persistent and probably less easy to check than hæmorrhage from a gastric ulcer. It is undoubtedly more insidious, for I have seen patients blanched and breathless from loss of blood who have never suspected that their "indigestion" was in any way connected with the cause of their condition. Other signs and symptoms may appear later, due to the changes which occur in the duodenum and stomach as a result of the induration or puckering of the ulcer. These are precisely the same as those which are caused by stenosis of the pylorus and need not be discussed in this connexion.

The complications of duodenal ulcer.—These are: (1) hæmorrhage; (2) perforation, acute, subacute, and chronic; (3) [illegible] the [illegible] at t [illegible] bile and pancreatic juice; (5) periduodenitis; (6) cancer; (7) compression of the portal vein from cicatrisation of a deeply placed ulcer (French); (8) diseases of the gall-bladder or bile-ducts; and (9) diseases of the pancreas.

1. *Hæmorrhage.*—Any of the vessels in or near the duodenum may be opened by the deepening of the ulcer. The following among the larger vessels have been perforat [illegible] ssais), gastro-duod [illegible] atico-duodenal (All [illegible] catica magna, and [illegible] porta (Rayer and Habershon) and the superior mesenteric vein (Warfwinge). The surgical treatment of hæmorrhage in copious quantity

from a duodenal ulcer is the surest means of arresting it. As soon as there is evidence that the hæmorrhage is persisting there is urgent need for surgical measures. The indication to operate is in my judgment more imperative than it is in cases of gastric ulcer, for the bleeding more often implicates larger vessels and is less likely to cease spontaneously. In all my cases I have performed gastro-enterostomy alone and have not removed or sutured the ulcer; in all cases the hæmorrhage has ceased at once. There are cases, however, in which I think that an excision of the ulcer if easily accomplished would be desirable, and there may be cases where the ligature of a large vessel in the ulcer would be necessary. In some cases closure of the pylorus by infolding sutures may be practised. In many instances, however, removal of the ulcer would be impossible and in the great majority it probably is neither necessary nor desirable. Gastro-enterostomy in all cases is the operation of choice; and it must be performed whether the ulcer is treated separately or not in order to give rest to the duodenum.

2. *Perforation.*—The frequency of perforation in duodenal ulcer is given by Collin as 69 per cent. and by Chvostek as 43 per cent. It is generally stated that perforation is more likely to occur in duodenal ulcer than in gastric ulcer, and that having occurred its consequences are more disastrous. Pagenstecher estimated the mortality of perforation at 86 per cent. In my former paper I collected notes of 51 cases of perforation treated by operation with eight recoveries. My present list embraces a series of seven cases upon which I have operated, with five recoveries. The remarkable mimicry of appendicitis, to which I called attention, has been confirmed by the observation of other writers. It is due, as I have shown, to the direction which the extravasated fluid takes—down the hillock to the right of the transverse mesocolon, down the ascending colon to the iliac fossa. In my series of 51 cases no fewer than 19 had been operated upon after an erroneous diagnosis of appendicitis had been made. When chronic or subacute perforation occurs an abscess may form. Meunier describes a local abscess in his case as being bounded by the quadrate lobe of the liver, the gall-bladder, and the transverse mesocolon. Lennander relates a case where an abscess was hemmed in on all sides by intestine. The perforation of such an abscess may lead to acute septic generalised peritonitis, as recorded by Planchard. Perforation of the upper portion of the duodenum may lead to subphrenic abscess. Seven cases of this kind are related in Maydl's monograph. An ulcer may destroy all the coats of the bowel and its base be formed by the liver (Keyl, Herzfelder, Collin) or by the gall-bladder (Krauss, Moynihan). An ulcer may destroy all the coats of the bowel and perforate a hollow viscus forming an "internal duodenal fistula." Rokitansky describes a case of gastro-duodenal fistula; Hoffmann and Gross cases of cholecysto-duodenal fistulæ; Murchison, West, and Sanderson cases of duodeno-colic fistulæ; and Dudensing a case where the ulcer had perforated the pancreatic duct. An ulcer may destroy all the coats and lead to the formation of an abscess which bursts upon the surface of the body, forming an "external duodenal fistula," as recorded by Lumeau and Bucquoy. The duodenal wall may be ulcerated through by an abscess arising from without, as in a case of lumbar abscess bursting into the duodenum close to the biliary papilla, under the care of Davies-Colley.

3, 4, 5, 6, and 7 have been considered at length in my former paper; I have nothing to add to the detailed descriptions given therein.

8. *Diseases of the gall-bladder and bile ducts.*—The associated conditions of pancreatic and gall-bladder disease are of great interest. In ten cases in my series there was obvious evidence of disease in the gall-bladder or bile-ducts, with or without gall-stones. I have in some cases performed gastro-enterostomy and cholecystotomy or cholecystectomy. From one patient I removed 1885 gall-stones. The disease in the duodenum may be primary and that in the gall-bladder secondary, or that in the gall-bladder may be primary and that in the duodenum secondary, or the two may be entirely independent. Duodenal ulcer may dispose to the formation of gall-stones by giving rise to peritonitis. As a result of this there is stasis of bile and perhaps infection—the two conditions which we know to be essential to the development of gall-stones. On the other hand, a condition of cholecystitis, whether calculous or not, may cause disease in the duodenum in a manner well illustrated by one of my cases. The gall-bladder had contained a single large stone which had ulcerated through into the duodenum, which it blocked. The duodenum, gall-bladder, and stone were massed into one dense tumour which both felt and looked very like a malignant growth. The "gritty" surface which I have long felt to be an invariable accompaniment of malignant disease was not present and a closer investigation of the lump was made and the condition I have described was revealed. The symptoms and the signs of duodenal ulcer are in some cases not easy to distinguish from those which are due to cholelithiasis. The pain in both may be colicky or it may be persistent; the direction in which the radiation extends may be similar; there is in both conditions, as Ewald has shown, an excess of free hydrochloric acid. The discrimination between the two may, therefore, not always be possible, but in the cases, as I have seen them, there has been little or no difficulty in making a correct diagnosis. Happily in both cases surgical treatment offers the speediest and safest relief.

9. *Diseases of the pancreas.*—The association of disease of the pancreas with duodenal ulcer has not received attention. It was present in three of my cases. A duodenal ulcer may in its gradual deepening destroy all the coats of the bowel until the pancreas is reached. The base of the ulcer is then formed by the pancreas which is implicated in the inflammatory process. A localised chronic pancreatitis results, or if the inflammatory process be more acute an abscess may form. A condition of chronic pancreatitis may be present in cases of duodenal ulcer and be caused by the same condition as gave rise to the ulcer—alcohol for example, or perhaps syphilis.

The following is a brief extract from the notes of the cases upon which I have operated. The cases are arranged in three series: Series 1 includes the cases of perforating ulcer; Series 2 includes the cases of duodenal ulcer; and Series 3 includes the cases of associated gastric and duodenal ulcers.

SERIES I.—*Perforating Duodenal Ulcer (Seven Cases).*

Males	4	Deaths	2
Females	3	Recoveries	5

CASE 1.—April 26th, 1900; male, aged 44 years. Symptoms had been present for 18 months; the chief of them was pain two, three, or four hours after food. Blood had been observed when the patient vomited; vomiting was frequent but irregular. There was no melæna. On the 25th while in the infirmary the man became suddenly worse; pain came on acutely in the whole abdomen. Distension and rigidity were soon observed. Collapse was pronounced. The respirations were 28 and the pulse was 128. A diagnosis of perforating ulcer was made and the abdomen was opened. The ulcer was found at the beginning of the second part of the duodenum; its diameter was about three-quarters of an inch. After stitching the ulcer up the gut seemed narrowed to at least half its diameter. A gastro-enterostomy, with the aid of a Murphy's button, was therefore performed. The patient never rallied from his collapse. Time of operation after perforation about 26 hours.

CASE 2.—June 18th, 1901; male, aged 25 years. The patient, a sturdy robust labourer, stated that for about four weeks before admission he had suffered from indigestion and vomiting. On the 18th, while climbing a ladder he was suddenly seized with intense abdominal pain. He was seen at once by a medical man who happened to be near and was sent to the infirmary. He was then profoundly collapsed. Breathing was quick and short; his pulse was 128; the abdomen was rigi[illegible] agnosis of perforated ulcer was made. At the [illegible] equal in diameter to a No. 8 or 9 catheter was [illegible] m one inch from the pylorus. The ulcer was stitched and the abdomen was cleansed and drained. The patient recovered. Time of operation after perforation 3 hours 50 minutes.

CASE 3.—April 20th, 1902; female, aged 17 years. For several weeks she had had slight indigestion and epigastric pain but not in sufficient severity to send her to a medical man. On the night of April 19th at 9 P.M. she had a sudden attack of acute epigastric pain. Morphine was given. She was seen at 7 A.M.; the abdomen was very rigid and rather tender, especially over the gall-bladder. She had vomited once. The pulse was 112. Respiration was very shallow. At the operation an ulcer was found to have perforated on the anterior surface of the duodenum, about three-quarters of an inch from the pylorus. There was some fluid above the stomach. The ulcer was closed by suture and the peritoneum was cleansed by wiping with swabs wet with sterile salt solution. There were no lavage and no drainage. The patient recovered. Time of operation after perforation about ten hours.

CASE 4.—Dec. 27th, 1903; female, aged 17 years. She had always been pale and anæmic and for 12 months had complained of indigestion and occasional vomiting. I[illegible] enly four days before admission with pain i[illegible] ss the abdomen. There was vomiting. At the [illegible] denal ulcer was found. An incision was mac[illegible] fensive pus was found. Tubes were inserted. The patient recovered and is now in sound health. (A case of subacute perforation.)

CASE 5.—March 24th, 1904; female, aged 25 years. She had had indigestion for 12 years. For many years she had had acid eructations and for the last two years had vomited after food. She had had many severe attacks of pain in the epigastrium. Four days prior to admission and again one day before she had attacks but not any more acute than many she had had previously. During the last three years her weight had dropped from 9 stones to 5 stones 8½ pounds. At the operation there was found to be a perforation of the size of a small pea in the upper part of the first portion of the duodenum. The ulcer was of about the size of a half-crown. There was a little local plastic peritonitis but no general infection. The perforation was closed by Lembert's sutures and a posterior gastro-enterostomy was performed. The patient recovered.

CASE 6.—May 11th, 1904; male, aged 22 years. He had been quite healthy up to the beginning of April, 1904, when he felt a slight pain in the abdomen. This only lasted a few minutes and then passed off Three weeks l[illegible] Within three [illegible]

[illegible] ptoms of a similar kind again [illegible] At the operation an incision was made over the appendix. The appendix was found lying along the [illegible]

and rigidity [illegible] the area of [illegible] was present [illegible] was not so [illegible] pulse was 1[illegible] tenderness and dulness as before. On the 11th his general condition [illegible]

tines. In the anterior wall of the first part of the duodenum an aperture of the size of a large quill was found. This was closed by sutures and sequestrated by stitching that surface of the duodenum to the stomach wall. Free drainage was made through both loins and from the pelvis. The patient died 11 hours after, despite infusion (twice) and the usual stimulants Post mortem an ulcer on the posterior wall of the duodenum, just beyond the pylorus, was found. It was an ulcer on the anterior wall which had perforated.

SERIES II.—*Duodenal Ulcer (22 cases).*

Males	14	Hæmatemesis and melæna ...	4
Females	8	Hæmatemesis alone	3
(There was 1 death.)		Melæna alone	2

CASE 1.—August 7th, 1902; male, aged 31 years. There was a ten months' history of pain after food and gradual loss of weight. All solid food had been abandoned little by little and now a fluid diet caused pain, occasional vomiting in large quantity, and distension. He had twice had hæmatemesis The pain was frequently felt about from one and a half to two hours after food; it was slight at first but gradually increased in intensity. It was always relieved by a meal or by taking small quantities of biscuit He was often wakened at 2 or 3 o'clock in the morning by the pain. He had sour and bitter eructations. He had lost exactly 4 stones in the last 19 weeks. He had a very dilated stomach. Free hydrochloric acid was present in excess. At the operation, while lying under the anæsthetic on the table, the dilated stomach showed prominently. It descended a hand's breadth below the umbilicus. On opening the abdomen a thickening of the duodenum above the bile papilla was felt, the first portion of the duodenum and the stomach were very markedly dilated. Posterior gastro-enterostomy was performed The pati[illegible] ood before leaving hospital. [illegible] and slight pain but has eate[illegible] eight. On Oct. 20th he ha[illegible] s "feeling stronger."

CASE 2.—Sept. 24th, 1902; male, aged 32 years. On April 9th of this year the patient was suddenly seized with an acute attack of pain in the right hypochondrium. He vomited frequently and some blood was noticed. The attack lasted two hours and subsequently the motions were seen to be tarry. Since then he had suffered almost constantly from flatulent distension of the abdomen, especially after food. On several occasions he had had very severe attacks of pain in the right [illegible] ibling him up." Each [illegible] and on two occasions [illegible] n was chiefly situated [illegible] painful spot could be [illegible] jaundice. He had lost [illegible] The stomach was a [illegible] ss. At the operation [illegible] portions of the duo- [illegible] a walnut, very thick and adherent to the pancreas. Posterior gastro-enterostomy was performed. The gall bladder was found to be [illegible] full of stones. [illegible]

CASE 3.—Sept. [illegible]th, 1902, female, aged [illegible] years. She had been failing in health for from nine to ten months. The chief symptom had been vomiting. At the onset she had a sudden seizure of vomiting, [illegible] health.

CASE 4.—Oct 4th, 1902, male, aged 29 years. He had suffered for several years from a "weak stomach," having pain after food, two or [illegible] "dead tired"; and the bowels were moving frequently and on all occasions blood was coming When seen he looked desperately ill. His face and mucous membrane of the mouth were blanched to the last degree. Chronic duodenal ulcer, with acute deepening and the opening of some large vessel, was diagnosed. Operation was advised as a last resort. On opening the abdomen the stomach was found to be very dilated and full of gas; it contained no blood. The first portion of the duodenum was also dilated. About one inch from the pylorus a dense hard mass equal in size to a walnut was felt adherent to the pancreas Excision of this ulcer [illegible] enterostomy was performed T[illegible] and cold and then [illegible] April of this year [illegible] a duodenal ulcer. [illegible] well but she was never able to take [illegible] two months the stomach had been [illegible] taken. Pain and discomfort after [illegible] and the ileum [illegible] free from adhes[illegible] stomach was found There was a duodenal ulcer equal in size to a sixpence Posterior gastro-enterostomy was performed The patient recovered. He had a severe attack of bronchitis after the operation, with high temperature and rapid pulse [illegible] ale, aged 31 years He had been [illegible] two or three years. He now had pain [illegible] s eased by food He [illegible] eal and belched very [illegible] began to feel a sinking [illegible] of the hand over the [illegible] to the right of the [illegible] gel. Gastric hyper- [illegible] duodenal ulcer about [illegible] ne surface and hard [illegible] nd Posterior gastro-enterostomy was performed. The patient recovered. (Dr Lammerer and Dr. Brewer of New York were present.) The result of the operation has been perfectly satisfactory.

CASE 8.—July 14th, 1903; male, aged 42 years. For many years he had had indigestion. He had pain, burning, and fulness after meals. The pain came on about two hours after a meal and lasted till the next meal, when he was easy for a time. The pain went round the right side of the abdomen and through to the back. He had recently become much worse and had a heavy, burning feeling in the pit of the stomach. He could not eat with comfort. There was no vomiting. He was very tender in the right of the epigastrium. At the operation a duodenal ulcer was found just beyond the pylorus. There was a circular reddened [illegible] area. There were a few adhesions on [illegible] omach. Posterior gastro-enterostomy was performed. The patient recovered and has since been perfectly well and able to eat ordinary meals heartily. He has gained one and a half stones in weight.

CASE 9.—August 7th, 1903; male, aged 39 years. Some years ago the patient had five or six attacks of severe abdominal pain with fainting. The last of these was four years ago. Since then he had suffered a good deal from indigestion, pain from two to four hours after food, sometimes earlier than this, though not usually. He suffered much from flatulent distension after a meal and had very sour eructations. On July 27th, 1903, he had another similar attack of pain and nearly fainted. The pain passed off in about half an hour. On August 1st his motions were quite black; he felt quite well. On the 8th while cycling home from business he felt faint and got off his bicycle. He vomited a large quantity of blood. On reaching home he collapsed. Next day he again vomited blood and had several black stools. He was anæmic and his pulse was 120. At the operation an ulcer was found on the posterior wall of the second part of the duodenum, adherent to the pancreas. Posterior gastro enterostomy was performed. The patient was severely collapsed after operation but he recovered. The result of operation was perfect. In June, 1904, he was quite well.

CASE 10.—Nov. 23rd, 1903; male, aged 30 years. The patient was quite well up to 18 months ago, when he had an attack of pain below, and to the right of, the umbilicus, accompanied by vomiting. These [illegible] intervals up to now; latterly he had only [illegible] early morning. The pain came on as a rule [illegible] after a meal; during this hour or more he was more comfortable than at any other time. The heavier the meal the longer his freedom from pain. Dieting did not improve the condition at all. No hæmatemesis or melæna had been noticed although looked for recently. At the operation there was found to be thickening and puckering of an old ulcer in the first part of the duodenum. Posterior gastro-enterostomy was performed. The patient recovered and has since been perfectly well. He eats heartily and has no discomforts.

CASE 11.—Dec. 2nd, 1903; female, aged 45 years. The patient had pain after food and occasional vomiting for ten years. She was much worse the last three months. She had lost one stone in weight [illegible] the last eight months. Examination of [illegible] showed absence of free hydrochloric [illegible] At the operation a thickened band was found across the front of the first part of the duodenum. There were many adhesions of omentum to the anterior wall of the abdomen. Posterior gastro-enterostomy was performed. The patient recovered.

CASE 12.—Dec. 3rd, 1903; female, aged 38 years. The patient had had symptoms on and off for ten years; they had been worse of late. There were vomiting, pain in the left side, and nausea. The pain was always present but worse after food. Vomiting made the pain worse. The patient said that she had vomited a little blood sometimes. The bowels were constipated. There was loss of weight. She now weighed 5 stones 4½ pounds. There were frequent vomiting and tenderness over the left hypochondrium. Free hydrochloric acid was in excess in the stomach contents after test meals. The urine was acid, of specific gravity 1018; albumin was present but no sugar. At the operation nothing abnormal was found. There were no scars. Posterior gastro-enterostomy was performed. The patient developed hæmaturia and uræmic symptoms and died on the 8th.

Necropsy.—There was no peritonitis and union was quite sound. "Kidneys are small and present cysts on their surfaces. The capsule does not strip readily, being adherent in some places. On passing the finger over the surface of the kidney a distinctly granular impression is imparted to it. The cortex is extremely narrow, almost all the kidney substance being made up of the pyramids. The pelves appear normal." There was ulceration without induration in the duodenum, probably uræmic in origin.

CASE 13.—Jan. 15th, 1904; male, aged 32 years. Symptoms had been present for three or four years. There was pain at first during a meal, later an hour or so after food. For 18 months there had been vomiting. The loss of weight amounted to one and a half stones. There was no hæmatemesis. At the operation there were adhesions of the pylorus and the duodenum to the gall-bladder. The duodenum was dilated. Posterior gastro-enterostomy was performed. The patient recovered.

CASE 14.—Jan. 20th, 1904; male, aged 40 years. The patient had suffered from pain in the epigastrium for 18 years. During the last three years this had been worse and he had had occasional attacks of vomiting. For six months the pain had been very severe. There had been a feeling of heat and oppressiveness in the epigastrium and there were [illegible] gurgitation of food. He had lost 14 pounds in [illegible] No free hydrochloric acid was present. At [illegible] l ulcer of the size of a threepenny-piece was found just beyond the pylorus. Posterior gastro-enterostomy was performed. The patient recovered. After the operation he could take food well but there were still a good deal of flatulence and distension of the abdomen.

CASE 15.—March 24th, 1904; female, aged 25 years. The patient had had indigestion for 12 years. For many years she had had acid eructations, distension, and for the last two years had vomited after food. She had had many severe attacks of pain in the epigastrium, beginning, as a rule, an hour or two after food. Four days before admission, and again one day before, she had attacks, but not any more acute than many she had had before. During the last [illegible] dropped from 9 stones to 5 stones 8¾ pounds. [illegible] of the size of a small pea was found in [illegible] portion of the duodenum. The ulcer, with the induration around it, was of about the size of a half-crown. There was a little local plastic peritonitis but no general infection. The perforation was closed with Lembert's sutures and a posterior gastro-enterostomy was performed. The patient recovered. Since the operation she had eaten better than ever before and had gained about three stones in weight.

CASE 16.—June 17th, 1904; male, aged 40 years. The patient had suffered from indigestion for 20 years. 12 months previously he had a sudden attack of faintness, followed by anæmia and great general feebleness. He noticed that the motions were black for some days after the attack. There was no hæmatemesis. Six months previously a recurrence of these symptoms and commencing dilatation of the stomach were noticed by Dr. R. H. Trotter. Two similar attacks had since been noticed; in the last there was "profuse hæmorrhage." Great tenderness was present along the costal margin on the right side down to the umbilicus. There was some dilatation of the stomach. The pain generally came on from one to one and a half hours after food. At the operation a large duodenal ulcer was found about three-quarters of an inch beyond the [illegible] and opacity around it. Posterio[illegible] The patient recovered and since [illegible]

CASE 17.—June 17th, 1904; male, aged 40 years. The patient had had stomach trouble over 20 years, flatulence and pain coming on from one to one and a half hours after food At Easter, 1902, he noticed that the fæces were black and he once vomited blood. Ten days before he vomited a ver[illegible] "half a bucketful." At the operation [illegible] in the anterior wall of the first part of the duodenum, with adhesions to its surface. Posterior gastro-enterostomy was performed. The patient recovered and his medical man reports that he has made remarkable progress since the operation.

CASE 18.—July 16th, 1904; female, aged 26 years. For three years the patient had suffered from pain in the epigastrium and between the shoulders. This came on almost immediately after taking food and was very often followed by vomiting which relieved the pain. There [illegible] great fulness and oppression and a burning pa[illegible] stomach after meals. There had been slight [illegible] or four occasions. At the operation a somewhat dilated stomach was found. There was a cicatrix on the anterior wall of the first part of the duodenum about a quarter of an inch beyond the pylorus. No obvious stenosis was present. There were adhesions to the under surface of the liver. Posterior gastro enterostomy was performed. The patient recovered.

CASE 19.—August 4th, 1904; male, aged 55 years. The patient had been subject to occasional attacks of pain for several years. The pain was very definitely localised over the upper part of the right rectus. It came on at night and lasted two or three hours. He rarely vomited He had occasionally been slightly jaundiced. While in hospital he passed a considerable quantity of altered blood per rectum. He was very thin, anæmic, and prematurely aged. At the operation a mass of indurated tissue of about the size of a hen's egg was found involving the first part of the duodenum. It was considered to be an ulcer with surrounding inflammatory thickening. Posterior gastro-enterostomy was performed. The colon was quite blue in colour from contained blood. The patient recovered.

CASE 20.—August 17th, 1904; male, aged 52 years. The patient had been ailing for about 12 months severely but slightly for nearly three years. He first noticed pain in the stomach on waking at 2 or 3 o'clock in the morning; he would then vomit "nasty sour stuff." The pain had since increased very much and was now all to the right of the middle line, where there was tenderness. The pain came on from one to three hours after food. "Heaving," retching, and foul eructations were present. He had several attacks of severe vomiting but never of hæmatemesis. The stomach was large but there was no visible peristalsis. At the operation a duodenal ulcer was found. There were many adhesions of the stomach, duodenum, and omentum to the anterior abdominal wall high up. Posterior gastro-enterostomy was performed. The adhesions were not separated. The patient recovered.

CASE 21.—Sept. 2nd, 1904; female, aged 44 years. There was an indefinite history of an attack of abdominal pain after confinement about 11 years previously. The patient was in her usual health at the beginning of this year, though occasionally she had had attacks of dizziness and abdominal pain. In January, 1904, she began to feel pain after food. Soon vomiting began which relieved the pain. The vomit was very offensive. She had lost about two stones in weight. Free hydrochloric acid was present in the stomach contents. The stomach was much dilated and greatly hypertrophied. Contractions were constantly seen. At the operation the stomach was found to be much dilated. There were extensive adhesions between the pylorus, the gall bladder, and the lower margin of the liver. Gall stones were felt in the gall-bladder. Posterior gastro-enterostomy was performed; then the adhesions between the liver and the first part of the duodenum were separated. The gall-bladder was intimately adherent to the duodenum In separating this the duodenum was opened. A gall-stone of about the size of a pigeon's egg was found projecting into the duodenum but covered completely, or almost completely, by duodenal mucosa. The wound in the duodenum was sequestrated by suture. The gall-bladder, which contained another stone, was small and shrunken; it was removed. A drainage-tube was left in the cystic duct. A split tube with a gauze wick was left in the kidney pouch. The patient recovered.

CASE 22.—Sept. 3rd, 1904; female, aged 40 years. The patient was confined 11 weeks previously. Three weeks after labour she began to feel very weak and languid and one day she noticed that her motions were quite black. They continued to be so for eight or ten days. She had only vomited once, the vomit, according to her medical attendant, containing about one ounce of blood. She had never had any pain in the abdomen but she had been unable to take solid food on account of its bringing on palpitation. At the operation an ulcer was felt in the first part of the duodenum. The stomach was a little dilated. Posterior gastro-enterostomy was performed.

the patient had a severe attack of melæna Several years before this he had been subject to indigestion and inability to eat heartily, but for a few months before this attack of bleeding had been in better health than usual Since this attack he had had many others of melæna and hæmatemesis He had been in a nursing home in London for 13 weeks under treatment for duodenal ulcer and while there had had occasional severe bleedings and his hæmoglobin count was only 18 per cent. On examination he was very thin and anæmic. A dilated, obviously contracting, stomach was seen, from which he shortly afterwards vomited a quart of fluid containing blood. This patient looked very worn and ill. It was necessary to infuse saline solution during and after the operation. The day and night before operation he had copious melæna. At the operation an enormous stomach, slightly hypertrophied, was found. The first portion of the duodenum was imbedded in a mass equal in size to a lemon; there was inflammatory thickening round an ulcer. On the greater curvature there was an induration equal in size to a shilling near the pylorus. Posterior gastro-enterostomy was performed. The patient recovered. He was soon able to take ordinary diet. By March he had gained seven pounds. He had a severe attack of diarrhœa lasting four days in the fifth week. In July, 1903, he had gained four stones and could eat heartily. He was quite well in July, 1904.

CASE 15.—Feb. 9th, 1903; female, aged 56 years. In February, 1892, the patient was in the infirmary for removal of an ovarian cyst. In the notes it is said that she then suffered much from indigestion and on one occasion had melæna. Since then Dr. Woods had attended her for chronic indigestion. On several occasions there had been severe melæna. In December, 1901, hæmatemesis occurred. In 1887 a medical man diagnosed an acute illness as "ulcerated stomach." She now had pain two or three hours after a meal all over the upper part of the abdomen and frequently "heaving and vomiting." She could take nothing solid except biscuits, which she took to relieve the pain as soon as it came on. During the last twelve months she had lost over three stones in weight. attack of melæna. She had mass of the size of a the duodenum. Th he overlying peritoneum. In the sto about four inches from the pylorus, was an ulcer equal in size to a sixpence. The omentum was crumpled up and adherent over it. The patient recovered.

CASE 16.—Feb. 19th, 1903; male, aged 62 years. He had suffered from indigestion and vomiting for several years. He said that he did not remember when he was able to take an ordinary meal in comfort. Three years ago he was seen by a physician who diagnosed pyloric stenosis and gastric dilatation and advised operation. Since then the vomiting and pain had increased to such a degree that the patient said he "cannot go on any longer." On examination there was an enormous stomach actively contracting. At the operation a large hypertrophied stomach was found. There were several scars on the stomach. The pyloric region on both gastric and duodenal sides was scarred and stenosed. Posterior gastro-enterostomy was performed. The patient recovered. In May, 1904, he had gained two and a half stones in weight.

CASE 17.—April 11th, 1903; female, aged 19 years. Her first symptoms were observed in September, 1901. She had quite at the beginning an attack of hæmatemesis. She was then under careful treatment for over six weeks. When she began to take solid food the pain was noticed, generally half an hour after a meal. Vomiting and pain were constant after all solid foods, so that for "several months" she had lived entirely on fluids. For over three months now the pain had been increasingly severe and she had given up her work. Recently she had had a slight attack of hæmatemesis. The stomach was slightly dilated. At the operation ulceration was found near the cardiac end about one inch below the lesser curvature. There were some adhesions round the pylorus and duodenum involving the gall-bladder and surroundings. Posterior gastro-enterostomy was performed. The patient recovered.

CASE 18.—June 9th, 1903; male, aged 30 years. About 15 months ago the patient first noticed a sharp burning pain in the epigastrium a little to the left of the middle line. This was worse after food at first but latterly he had had most pain when fasting. He now felt easy when a moderate meal was taken, but in about an hour had "very bitter belching and waterbrash," and then pain became steadily more acute. He had vomited rarely until recently. He was now losing weight—one stone was lost in the last five weeks. The stomach was slightly dilated. At the operation a duodenal ulcer in the first portion about one inch beyond the pylorus was found. There was a hard pellet of scar tissue in the posterior wall of the stomach about two to three inches from the pylorus. The patient recovered. His weight before operation was 8 stones 3 pounds. On Sept. 9th, 1903, it was 8 stones 8 pounds; and on Sept. 3rd, 1904, it was 9 stones 1 pound.

CASE 19.—July 25th, 1903; male, aged 30 years. For several years he had suffered on and off from indigestion and had to be careful and sparing in his diet. Two months ago he had profuse hæmatemesis and for several days melæna. He fainted. Since then he had been kept in bed on very small quantities of liquid food but these give him pain and any attempt at increase caused vomiting. At the operation a duodenal ulcer was found immediately beyond the pylorus. There was a gastric ulcer near the greater curvature about three inches from the pylorus—a dense, white, very hard scar. Posterior gastro-enterostomy was performed. The patient recovered and has since been perfectly well.

CASE 20.—Dec. 2nd, 1903; male, aged 35 years. For two or three years the patient had had slight pain and discomfort after food, with foul and sour eructations. He began to vomit about one year ago, the act being sometimes induced in order to relieve his pain. No hæmatemesis or melæna was noticed. The stomach reached one inch below the umbilicus. At the operation the scar of an old ulcer was found on the posterior surface of the stomach near the lesser curvature. An ulcer of about the size of a sixpence was also found in the concavity of the first part of the duodenum. The patient recovered. Since the operation he has gained over two stones in weight and "can eat anything."

CASE 21.—Dec. 23rd, 1903; male, aged 28 years. The patient had suffered for six years from indigestion. There was pain in the epigastrium and between the shoulders after food. He was much troubled by a feeling of distension. There was no vomiting. At the operation a large scar with thickening on the posterior surface of the stomach was found, also considerable thickening in the duodenum. Posterior gastro-enterostomy was performed. The patient recovered. For some weeks after the operation he complained of a burning pain in the pit of the stomach, especially when fasting. Large doses of alkalies relieved him and he was in good health and free from pain in July, 1904.

CASE 22.—Jan. 27th, 1904; female, aged 61 years. For the last three months the patient had pain and fulness after food but no vomiting. The pain came on about half an hour after food. On examination a large stomach was found. A tumour was felt beneath the upper part of the right r deposit was found round us. There were no gall-st which was greatly indurated and enlarged at this part. There was a big and thick stomach. Posterior gastro-enterostomy was performed. The patient recovered.

CASE 23.—July 15th, 1904; male, aged 25 years. The patient had had indigestion for three years. He had a feeling of fulness before he had taken half a meal, followed by severe pain. He had never vomited except when he made himself sick in order to get rid of the fulness. At the operation the stomach in the pyloric region and the first part of the duodenum were found to be adherent to the under surface of the liver. Scars were also found on the posterior surface about two inches from the pylorus. ? Recent perforation. Posterior gastro-enterostomy was performed. The patient recovered.

Leeds.

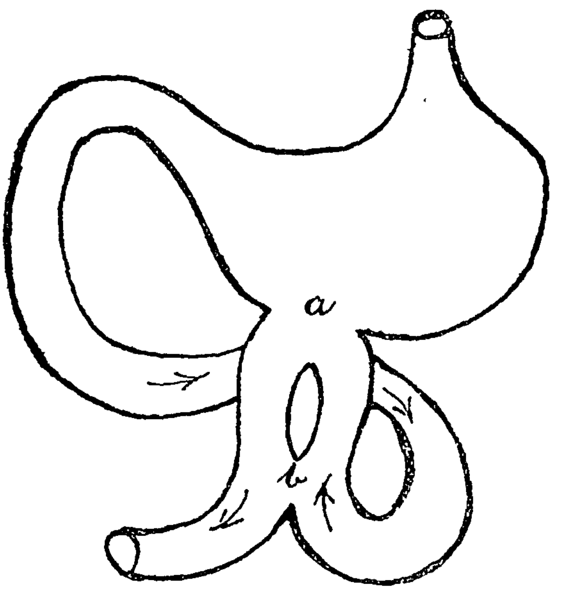
THE SEPTIC ORIGIN OF GASTRIC AND DUODENAL ULCERS.

BY W. BRUCE CLARKE, M.B. OXON., F.R.C.S. ENG.,

SURGEON TO ST. BARTHOLOMEW'S HOSPITAL.

IT is pretty generally acknowledged that the cause of gastric and duodenal ulcers is wrapped in obscurity. Any facts, therefore, that tend to elucidate this question are worthy of notice. This must be my excuse for the following few remarks on a case on which I have recently performed a gastro-jejunostomy.

The patient, a man, aged 55 years, was admitted under my care early in November, 1904, suffering from a gastric ulcer for which he had been treated at intervals during the last six years. His history, which has been fully verified by subsequent inquiries, is as follows. He is a sailor, an occupation which he has followed for many years. Just six years ago he was shipwrecked and spent 16 days in an open boat before he was picked up. During that time he suffered greatly from exposure and had nothing to eat but some mouldy maggoty bread and the water he drank was putrid. Two days after he was rescued he suffered from violent pains in the stomach and vomited everything he took for five days. He said that the vomit at that time was yellow and then became black. He had never been well since for any length of time but had suffered from attacks of pain and vomiting, usually about once a fortnight, and had always been obliged to be very careful about his diet ever since. Previously he enjoyed the best of health and could eat anything. He had been under medical treatment off and on during the whole time, in addition to being under the care of Mr. J. R. Kingdon in the wards of the Lynn Hospital, where rest, rectal feeding, and washing out of the stomach had had full trial but without any permanent benefit. In these circumstances I decided to explore the abdomen and to perform a gastro-jejunostomy if necessary. When the abdomen was opened and the finger was



introduced a large amount of thickening was felt in the region of the pylorus, extending both towards the stomach and the duodenum. The stomach was somewhat dilated. The operation of retrocolic gastro-jejunostomy was performed, the portion of jejunum selected being about seven or eight inches from the commencement of that part of the intestine. The stomach and jejunum were joined by a double row of continuous stitches, the mucous membrane being united by catgut and the peritoneal and muscular coats by silk (see diagram (*a*)). In addition to this, a jejuno-jejunostomy (*b*) was performed at the same time so as to avoid any chance of a vicious circle being set up, a plan which I now generally adopt. The arrows indicate the direction of the natural flow of intestinal contents and the purpose which is served by the double opening, (*a*) serving for the passage of stomach contents directly into the jejunum and (*b*) allowing the bile and pancreatic fluid to pass directly down the intestine without first mounting into the stomach.

Mayo Robson and Moynihan[1] make the suggestion that oral sepsis is responsible for many gastric ulcers, a view with which I quite concur, but I have never before come across a case in which the clinical evidence of this view was presented in so striking a fashion. It seems to me, therefore, worthy of record. Anything which emphasises the dangers of oral sepsis deserves to be recorded.

Harley-street, W.

THE RÔLE OF AN EXCESSIVE MEAT DIET IN THE INDUCTION OF GOUT.

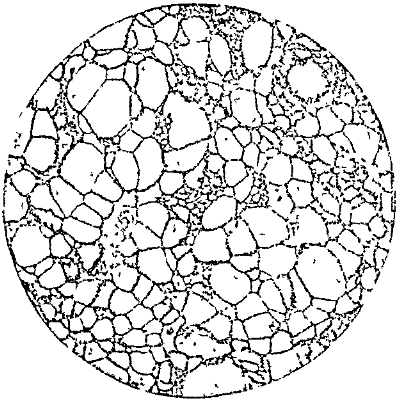
BY D. CHALMERS WATSON, M.D. EDIN., F.R.C.P. EDIN.,
LATE PHYSICIAN, MARSHALL STREET DISPENSARY, EDINBURGH.

IN 1904 I submitted evidence in favour of the view that there is an infective element in gout. This evidence was obtained from the examination of the tissues from a case of acute gout in a fowl[2] and from the histological examination of the tissues in chronic gout in man.[3] It may be some time before conclusive evidence of the existence of an infective element is available. If we provisionally accept this view the question naturally presents itself as to how far its adoption is in harmony with a well-established fact of the disease—viz., the importance of diet (solid and liquid). It appears to me that a belief in the infective nature of gout in no way minimises the importance of a study of diet and for this reason: if there is an infective element in the disease the main source of infection is the digestive tract and there is good reason to believe that the activity of the bacteria in the intestinal contents must depend largely on the character of the foodstuffs.

In view of the generally admitted fact that an excess of meat diet is prejudicial to most gouty subjects I have sought to determine by observations on animals whether an excessive meat diet exerted a specific action on any of the ductless glands. My results have shown that a diet of raw meat and water (Salisbury diet) exercises a very marked effect on the thyroid glandular system. The results obtained from investigation in poultry were communicated to the Physiological Society in March, 1904, and in December the results of a similar investigation on rats were communicated to the same society. The present paper is a *résumé* of the more salient features of these investigations from the clinical standpoint.

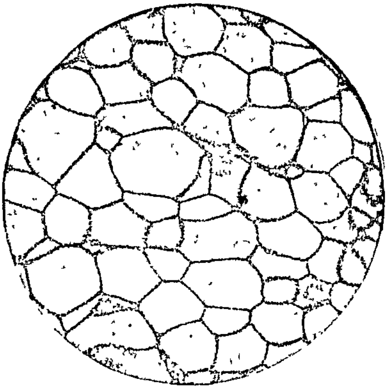
The effect of an exclusive raw meat and water diet on the thyroid and parathyroid glands in poultry.—As a result of feeding three healthy fowls on an exclusive raw meat and water diet for periods ranging from 13 to 16 months, a very striking hypertrophy of the thyroid and parathyroid glands was induced in all the animals. The parathyroid glands, instead of being microscopic structures, appeared as large glands, considerably larger than a pea; the thyroid glands were much enlarged and weighed from eight to ten times or more the weight of the normal gland. Histologically the parathyroid glands showed the normal appearance of parathyroid tissues; the thyroid glands presented the appearances characteristic of simple parenchymatous goitre in the human subject—viz. (see Figs. 1 and 2), great enlargement of spaces which were distended with colloid material, enlargement of the wall of the vesicles, and in some areas proliferation and shedding of the epithelial cells, with hæmorrhage into the vesicles. So far as I am aware, this is the first time that there has been induced experimentally in animals an enlargement of the thyroid gland similar to that seen in simple parenchymatous goitre in the human subject.

FIG. 1.



[illegible] (× 50) Observe [illegible] the walls of [illegible] ar glandular

FIG. 2.



Thyroid gland of fowl fed on raw meat and water. (× 50) Observe (1) the increase in size of the vesicles, (2) the increased thickness of wall of the vesicles; (3) the diminution in amount of intervesicular glandular tissue Cf Fig 1.

The effect of an exclusive raw meat and water diet on the [illegible] *glands in rats.*—As the result of an [illegible] which were fed on an exclusive [illegible] periods ranging from six weeks [illegible] was found that definite changes [illegible] gland in the great majority of [illegible] nature of the change was, however, quite different from that observed in the case of the poultry. The distinctive features were observed on histological examination (see Figs. 3 and 4), which showed (*a*) diminution in colloid material; (*b*) proliferation of the epithelial cells and also of the connective tissue; (*c*) evidence of rapid degeneration of the colloid into a mucinoid material; and (*d*) congestion of blood-vessels. Professor W. S. Greenfield kindly examined some of these specimens and pointed out to me that in the more marked cases the appearances bore a striking resemblance to those seen in exophthalmic goitre in the human subject. In the case of the one *adult* meat-fed rat, which succumbed after three weeks of the diet, the appearances of the gland were those of an advanced atrophic catarrh with complete absence of colloid. In the great majority of cases the parathyroid glands were normal. So far as I am aware, this is also the first occasion on which it has been directly shown that a particular diet induces distinct histological changes in the thyroid gland of an omnivorous animal (rat), and, further, that these changes are of a nature similar to those seen in the gland in cases of exophthalmic goitre in the human subject. It should be stated that the animals showed no other signs or symptoms of this disease.

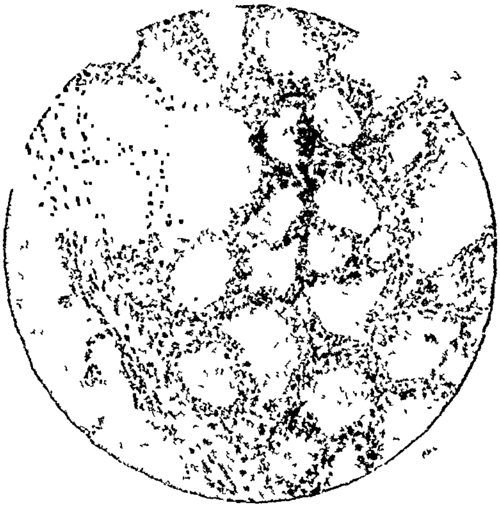
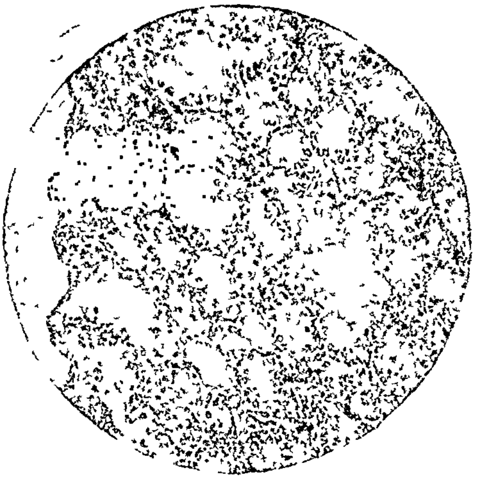
FIG. 3.



Thyroid gland of rat fed on bread and milk. (× 200) Observe (1) the size of vesicles and regularity of outline; (2) the colloid material in the vesicles. Cf. Fig. 4.

FIG. 4.



Thyroid gland of rat fed on raw meat and water. (× 200) Observe (1) catarrhal changes in the epithelium; (2) diminution of the colloid material.

Remarks.—The results obtained from the two investigations agree in showing that a diet of meat and water profoundly influences the thyroid gland. In poultry the diet induced a striking hypertrophy of the gland with great increase of colloid material which appeared for the most part normal. In the case of rats the striking change was the alteration in the character of the secretion with catarrh of the epithelial lining of the vesicles, the general appearance of the gland indicating exhaustion of its functions. Further investigations are necessary before the difference in the results obtained in the two classes of animal can be explained. In the meantime it appears to me that these new facts have some practical interest and importance. There are figures in the Blue-book which conclusively prove that there has been a great increase in the consumption of meat in this country in the past 30 years. Evidence is also accumulating to show that thyroid medication is of value in a number of diseased conditions which have no known relationship to the thyroid gland—e.g., skin diseases, mental affections, eclampsia, and other disorders. May not the new facts recorded in the present paper explain the value of thyroid medication in those cases? It is, I believe, possible that as a result of the excessive use of meat there has been established in many subjects an alteration in the character of the thyroid secretion, which defect is remedied in the cases in question by the administration of thyroid gland. The adoption of this view has led me in the past year to try the effect of the administration of small doses of thyroid extract in two inveterate cases of chronic gout which had not been amenable to dietetic measures aided by skilled balneological methods. In both cases the symptoms were relieved to a striking degree, this relief having been so far of a fairly permanent nature.

Edinburgh.

CARBONIC ACID AS A FACTOR IN THE GENESIS OF THE GOUTY STATE.

BY DONALD F. SHEARER, M.B. OXON., F.R.C.S. ENG.

THE origin of the gouty state, in which it is usual to group together clinically gout, arterio-sclerosis, and chronic interstitial nephritis, is commonly attributed to the over-production or the retention of uric acid or its salts within the body; and a bewildering wealth of chemical experiment, of pathological record, of physiological research, of clinical observation, and of polemical argument awaits him who seeks for further enlightenment. So overwhelming is the mass of literature on the subject that one is justified in putting it all aside in order to consider the question *de novo* and in avoiding the narrow purview of the test-tube or the microscope in order to seek a solution in a less restricted field of vision. We have learnt empirically that these pathological conditions are wont to follow long-continued excesses in diet and also upon deficient muscular activity and we also know that lead poisoning has a definite etiological relationship to them. On the first two we have built our prophylactic and our curative treatments and from them it is possible to trace the genesis of the diathesis. It is interesting to note that notwithstanding all our investigations the modern treatment follows exactly the lines laid down in the days when uric acid was unheard of or had not been causally related to gout This fact, moreover, which can be verified by a reference to Sir T. Watson's lectures, indicating as it does that uric acid has led us into a blind alley barring further progress, is an additional reason for a wider review.

Now when we have to deal with a common phenomenon following upon diverse antecedents so various as undue indulgence in alcoholic drinks, excessive consumption of nitrogenous food, excess of carbohydrate diet, and insufficient exercise, when we find a mitigation of the symptoms succeeding to an alteration of each separate antecedent as well as of all combined, we may rightly seek for a causal factor common to all the antecedents rather than make the assumption that the cause is other than the known antecedents. A reference to any text-book of physiology tells us that the one factor common to all the antecedents of gout is the tendency to the production of an excess of carbonic acid in the blood. The cardinal feature of muscular exertion is the large increase in the output of carbonic acid without affecting the nitrogenous excreta. Alcohol and carbohydrates can only produce as the end products of their combustion water and carbonic acid Nitrogenous diet increases metabolism not only of proteid but of carbohydrate and hydrocarbons and thus leads to an increased amount of carbonic acid. And just as the action of the antecedents tends towards an excessive manufacture of carbonic acid, so the treatment we prescribe, whatever object we have in view and whatever may be our preconceived theory, is actually directed to the diminution or the elimination of this waste product

There is further an *a priori* probability, derived from a consideration of the anatomical distribution of the lesions, that if there be any toxin circulating in the blood to which the lesions may be attributed that toxin will be one that should normally be eliminated by the lungs in respiration For the brunt of the disease is borne not by the joints in articular gout but by the arterial system and the kidneys to which are assigned the work of conveying the purified blood and of further purifying it, and when we remember that the chief, if not the sole, portal of exit for uric acid is through the kidneys [illegible] t all the organic phe [illegible] vell owe their genesi [illegible] normal excretion through the agency of the lungs It is not hard to conceive that such a toxic blood should have the power to inhibit the excretion of uric acid and lead to an accumulation in the tissues such as precedes the gouty paroxysm, while the actual paroxysm itself may be dependent on local deposition initiated by local causes There is then a natural likelihood that the toxin of gout is or ought to be, an excretion of the respiratory function and there is an actual factor common to all the antecedents—the excess of carbonic acid If carbonic acid is to be considered the *fons et origo mali*, if not the *materies morbi* it must be shown that the excess is sufficient to be appreciable and to alter the composition of arterial blood deleteriously, but it is not necessary that the excess should be large, for, to use a mathematical figure the integration of an infinite number of infinitesimal divergencies from the normal yields a finite result, and in the second place the toxic action of carbonic acid must be such that the sum of a large number of such intoxications would produce the organic and functional lesions characteristic of the gouty state

The normal daily excretion of carbonic acid is 800 grammes corresponding closely to the amount which the oxidation of typical normal diets would yield A man doing hard work will excrete much more largely—say, 1200 grammes—and in order to maintain his weight would have to consume food of corresponding weight and quality If now we supply such a quantity of food without permitting the muscular activity necessary to excrete it the man will either not assimilate it, or he will convert it into fat, or he will metabolise it and excrete it as carbonic acid We know that he does assimilate it, we know that only a very small part is converted into fat, and we are compelled to the conclusion that he does excrete it as carbonic acid In the absence of the muscular activity, which would naturally increase the rapidity of the pulse and the frequency and depth of respiration, and therefore the quantity of blood exposed to aeration, the exchange of carbonic acid with the air must be greater than normal Under normal conditions of feeding and blood tension six out of 48 volumes of carbonic acid escape, in the altered circumstances nine must be evolved, other conditions being equal, and in order that nine may be evolved the carbon dioxide tension of the blood must be increased, that is, it must contain something like 72 volumes per cent, since the exchange of gases is proportionate and not a mere overflow If that be so the arterial blood in such a case will contain over 60 volumes of carbonic acid per cent, and making every allowance for the increased respiration from other automatic agencies there is obviously a large balance of carbonic acid which can only be accounted for on the supposition that during a portion of the day at any rate the carbonic acid tension is such as to allow an extra excretion and in consequence an excessive accumulation of it in the arterial blood with such deleterious consequences as its toxicity may give rise to The important fact in this connexion is that whereas the normal and healthy man regulates to some extent his diet by his activity, the man whc [illegible] keep the necessary balance and [illegible] soaks his arterial system and l [illegible] charged with carbonic acid All the modes of computing the discharge of carbonic acid point to the same result, whether we estimate it directly or by the oxygen inhaled or by the carbon ingested In all cases we find that muscular activity, excessive discharge of carbonic acid, and increased diet go together and we are forced to the conclusion that the gouty individual who on an excessive diet produces, by virtue of the increased metabolism consequent on a nitrogenous diet or by an excessive consumption of carbon compounds, an increased quantity of carbonic acid which is not removed by the direct cardiac and pulmonary effects of exercise must rid himself of it by means of an increased carbonic acid tension of the blood

As corroborative evidence let me adduce the well known gout producers—ale and port A pint of ale contains an ounce of alcohol and an ounce of saccharine matter A pint of port contains also an ounce of sugar and some five ounces of alcohol The former will produce by combustion 100 grammes of carbonic acid and the latter 340, so that a pint of ale or a quarter bottle of port are approximately equivalent gout producers and raise the total carbonic acid to be excreted by 12 per cent It remains to ascertain what, if any, is the effect of an excess of carbonic acid in the blood It appears that it augments the activity of the vaso constrictor centre, thus leading to a general contraction of the small arteries The heightened blood pressure thus produced is increased by the direct irritative action of venous blood on the muscular coats of the arterioles and by the increased peripheral resistance which occurs within the capillary area One cannot but be struck by the correspondence between this description of the action of venous blood and that which obtains in the gouty condition under consideration and it is obvious that a frequent repetition of such a state would inevitably induce hypertrophy of the muscular coat And the analogy of lead, a marked vaso constrictor, which is admittedly a cause of gout, and of adrenalin, which has recently been adduced to account for arterio sclerosis, shows that there is no need to labour this point We may conclude then, that the sum of the small additions to the blood pressure which are consequent upon the excessive presence of carbonic acid is sufficient to account for the muscular hypertrophy But we have also to account for the fibrosis, for the hyperplasia of connective tissue which exists both in the outer coat of the arteries and in the stroma of the kidney If we assume that carbonic acid in excess in arterial blood is an irritative toxin, as the cause evidently must be we can see by analogy how these tissues which are the first directly subject to the action of arterial blood and are therefore the first to [illegible] action [illegible] l its [illegible] but on the supporting structure in which the venous channels run So, too, with the irritation of the secretion from carcinomatous cells, the effect is also to produce hyperplasia of connective tissue with subsequent shrinking, and we may therefore easily believe that the effect of the chronic irritation of blood overcharged with carbonic acid would be increased connective tissue

From the nature of the case it is not possible to show by direct experiment that either fibrosis or muscular hypertrophy follows upon excess of carbonic acid, nor is it any more possible to show that carbonic acid possesses an inhibitory function upon the renal secretion but there are examples which go to show that this is so in general and in particular with regard to uric acid We can show from the experience [illegible] excess of carbonic acid will produce a [illegible] certain well marked symptoms [illegible] miting and partial suppression [illegible] takes place we get a soft pulse and a return of cutaneous heat—i e, vaso dilatation instead of constriction—accompanied by profuse diuresis, the urine laden with urates And this form of migraine is attributable either to over consumption of food, especially alcohol, with insufficient exercise or to exposure to a vitiated atmosphere charged with excess of carbonic acid In addition to such cases of the temporary toxic action of excess of carbonic acid there are cases where persistent excess leads to chronic nephritis and arterio sclerosis An example of this occurred in a patient in whom one lung had been collapsed entirely for many years In her case any symptoms of uric acid if they existed escaped notice and must have been of the slightest, for she was practically an abstainer from meat Her difficulty in getting rid of the carbonic acid, made greater by the little exercise she took, led in the aggregate to the organic lesions Many other such cases could be adduced, as well as others of different nature, to show that all the three classes—gout arterial sclerosis and chronic interstitial nephritis—and in general all so-called uric acid conditions are inseparably bound up with antecedent conditions, of which the main factor and the common factor is the excess of carbonic acid in the arterial blood. One would argue, of course, from such cases that carbonic acid is the determining factor which decides whether or no uric acid shall be eliminated or retained. It is worth noting also that its power to limit the water secreted by the kidneys is not absolute, for it may be, and is in the later stages, entirely overborne by the high tension in the glomeruli while still retaining its controlling influence over uric acid. This latter, then, in this view, occupies a secondary place, it remains no longer an etiological factor but becomes merely a retained normal secretion which under certain conditions obtains a pathological importance by being deposited in the neighbourhood of a joint and becoming the active cause of a local inflammation. The primary place must be assigned to the unnatural excess of carbonic acid in arterial blood as the most potent factor in bringing about those changes which go to make up the gouty state.

Putney, S.W.

THE RATIONAL TREATMENT OF FRACTURES.

BY J. STAFFORD MELLISH, M.R.C.S. ENG., L.R.C.P. LOND.,
SURGEON TO TETBURY COTTAGE HOSPITAL.

RECENTLY I wrote a rough draft of a letter on the rational treatment of fractures which I intended to forward to THE LANCET when I had had time to elaborate it. The leading article on the subject which appeared in THE LANCET of Jan. 21st last, p. 172, at once confirms my opinion that there is much room for improvement in this branch of surgery and emboldens me to send for publication what I had written. The leading article in question says:—

> The lack of completeness in many of our results opens a way, and is responsible, for much of the bone-setting which abounds in this country to-day and it is necessary to consider closely the situation which presents itself. We can all treat with success an uncomplicated fracture, say, of the tibia. The fragments of the broken bone are carefully replaced, splints are bandaged on, and a few weeks' rest in bed produces a firm osseous union of the two portions of the bone. Hardly any deformity can be detected on rigorous examination or even with the aid of a skiagram. Yet when we regard the case from another aspect we see that the result leaves much to [illegible] there may be little fault to be found with th[illegible] it is far from being a perfect member. The [illegible] could before his accident. The knee-joint and the ankle-joint are stiff; the long confinement between splints has resulted in the formation of numerous bands of adhesions, whether within the joints themselves or in their neighbourhood; muscles and tendons may have shortened from the enforced rest and the pain and tenderness combine with the adhesions in limiting movement. The patient can hardly after six or eight weeks of rest do more than get about feebly with the aid of crutches After some months an increased mobility of the limb may be obtained and work may be resumed.

I am convinced that this state of things can, and ought to, be prevented in the vast majority of cases of fracture and would be if the methods which I follow and try to describe were commonly adopted. These methods include rubbing and as much freedom and movement as can be permitted in each individual case. Having been dissatisfied with the results of fractures which I have seen treated both in hospitals and in private practice by the ordinary methods of splints and so-called passive movement "administered by the surgeon" I have been at some trouble to apply any hints on the treatment of injuries which might tend to avoid the subsequent stiffness of joints and the muscular wasting which invariably follow the continued use of splints, plaster-of-Paris, and other rigid apparatus, and from a treatise on bone-setting by Dr. Wharton P. Hood, as well as from a later work by the same author on the treatment of recent injuries, I have learnt much which has been of the greatest practical use and which varies widely from the general tenor of the usual text-books.

We have all seen stiff and wasted limbs "go on strike" and become œdematous and painful on being called upon to perform their wonted movements, often taking a longer time to get into a healthy working condition physiologically after the bone was firm than the bone itself had taken to unite. For my part I have come to look upon the bone as being quite able to take care of itself if the surgeon, after having approximated the fractured ends, will give his chief attention to keeping the circulation of the limb in a healthy condition. For this purpose I find that the less splinting one can do with the better and dependence must be placed upon rubbing and movement of a voluntary kind. Where a splint has to be used as in fracture of the humerus, of the femur, or of both bones of the leg, rubbing must be practised and the patient be induced to move his joints voluntarily every day, the splints being taken off for this purpose and then being replaced. The rubbing must commence at the proximal end of the swelling in the region of the fracture and be directed towards the body—i.e., in the direction of the venous circulation, gradually working down to the distal portion of the swelling. As a student I was always taught that the joints above and below a fracture were to be secured and kept rigid, but this course invariably produces stiffness which has to be got rid of after the bone is united. For some time past I have followed the recommendations of the author of the works mentioned above and it is now my practice to endeavour to give the joints free play where possible and in this manner to prevent both wasting and stiffness, by encouraging the patient to move the joints, merely supporting the bone. The patient must be persuaded to flex, to extend, to rotate, and, in short, to execute all the movements that the joints are in the habit of performing voluntarily. This is a much more efficacious and to my mind a more rational proceeding than waiting a stipulated time from the occurrence of the accident, as is generally done, and then beginning so-called passive movement to be performed by the surgeon, for in the voluntary movement the nervous stimuli are called into use, while in the passive they are not and, in fact, there is generally more or less antagonism on the part of the patient. I will describe two cases which have recently come under my care, in one of which I saw the patient two hours after the accident and treated the case according to the plan already enunciated. The other patient had been treated in the more classical manner and I was called in eight months after the accident, when I found her suffering from a stiff knee and ankle, muscular wasting, and pain on attempting to walk.

CASE 1.—The patient, a man, aged 42 years, and weighing 15 stones, had fallen down and broken his leg. On seeing him some two hours after the accident I found the tibia fractured at the junction of the middle and lower thirds, the fibula being fractured somewhat higher up. There was a good deal of swelling. I first flexed the knee and rotated the thigh outwards, resting the knee on a pillow to check muscular spasm, and gently rubbed at the swelling for an hour, beginning at the upper end and gradually working downwards, but always rubbing in an upward direction, in this manner squeezing out of the tissues and passing on the effusion which had gathered there. One who has not tried this would be surprised to find the reduction in size that he will produce and the comfort that it gives to the patient. It is as well during rubbing to take advantage of gravity by elevating the limb when able to do so. I then, as I always do in cases of simple fracture, strapped the leg. To do this I used pieces of strapping about two inches wide, and having placed the broken bones in as good a position as possible I applied the plaster to the leg *from above the break downwards* to the ankle, not tightly, but just so as to support the limb, letting each succeeding piece of strapping overlap its predecessor by about one half. It will be noticed that the limb was strapped from above downwards. This is done in order that in the daily upward rubbing of the limb afterwards the strapping may lie the right way and its edges may not become displaced by the hand of the rubber. In some cases where it is difficult to apply the strapping with equal pressure on account of the shape of the limb, advantage may be taken of the American method of bandaging the legs of racehorses—i.e., by surrounding the limb with a layer of cotton wool or Gamgee tissue, filling up cavities with the wool and strapping over it, thereby producing equal pressure. Having strapped the injured part I applied a pair of Cline's splints and rested the leg on a pillow with the knee flexed in the ordinary way. The splints were removed twice daily and the limb was rubbed for half an hour, morning and evening, the leg being supported and the patient being persuaded to flex and to extend his knee and ankle. On the evening of the fourth day the plaster, being loosened by diminution of the swelling, was taken off and replaced, this being done at intervals as the case demanded. The splints after a week were kept in position merely by two webbing straps and the patient's wife (an intelligent woman) was instructed to undo the straps and to remove the top or inner splint night and morning for the rubbing. The patient being a very heavy and unwieldy man I did not let him have crutches till the fourth week. Previously to this he got out of bed with help and sat in a chair with his leg resting on a sloping stool made for the purpose; and five weeks after the accident he walked out with crutches, putting his toes to the ground. In another week he could put his weight on the leg and stand without crutches. *There was no wasting of the muscles or stiffness of the ankle* or knee.

CASE 2.—In the second case which I saw eight months after the fracture had occurred I found the patient in bed with a wasted limb, rigid ankle and knee-joint, and some swelling round the knee, especially over the inner side in the region of the internal semilunar cartilage. I carefully examined the limb and found that the fracture had been a very similar one to that which I have described above. The *history given me was that the patient had walked with a* stiff limb since the accident and could not get about except with a crutch and then with considerable pain. She was also suffering from crutch palsy. The limb was in a position of eversion and she complained of pain when it was moved. I suggested an anæsthetic, with permission to do what I considered necessary when she was under it. This, however, was refused but I was requested to try to do what I could without an anæsthetic. I first of all began with the ankle rotating and flexing it and felt some small adhesions give way, after which the patient could move the joint. I then proceeded to the knee, adopting the position described by Dr. Hood—i.e., placing the foot between my knees with the inner condyles on either side of the calcaneum, the whole length of the foot resting between the adductor muscles of the thigh. I rotated the leg and the thigh by means of turning my knees in a lateral direction, both internal and external, flexing in each position, meanwhile having kept my thumb on the tender spot on the inner side of the head of the tibia. When flexing the joint I felt and heard the adhesions give way. After this movement I placed my right forearm at the back of the kneejoint, flexing the knee still further with the other hand. There was some pain but the patient could at once flex both joints herself. I got her out of bed and made her hold the back of a chair for support and in this manner she walked across the room and back, bending both joints. The limb was rubbed every day and the patient was made to walk and now she gets about with a stick.

These, I think, are the cases which are somewhat neglected by the profession and which, as a rule, ought never to occur if the recent injuries were dealt with in the first instance in a rational manner. If they were handled with common sense (that rarest of qualities) we should no longer see the daily press teeming with the marvellous cures of the so-called bone-setter fraternity.

Tetbury.

PYLOROPLASTY.

REMARKS ON 17 CASES OF PYLOROPLASTY, WITH AFTER-HISTORY FOR PERIODS VARYING FROM TEN YEARS TO FIVE YEARS AND THREE MONTHS AFTER OPERATION.

BY RUTHERFORD MORISON, F.R.C.S. ENG. & EDIN.,
SURGEON TO THE ROYAL INFIRMARY, NEWCASTLE-ON-TYNE.

SINCE Feb. 16th, 1895, when my first case of pyloroplasty was published in THE LANCET, I have never ceased to believe that pyloroplasty was the best operation for stricture of the pylorus and it has been with some surprise that I have observed it steadily falling into disuse among the majority of surgeons in this country and in America. The reason for this, so far as I can discover, is that it has been tried and found wanting. If this be true no better reason could be given and the last word would have been said, but my experience does not confirm this idea. An operation which is simple and safe and which interferes in as small a degree as possible with the normal anatomy and physiology of the organs concerned ought, in my opinion, to be rejected only after weighty evidence against it has been produced. In suitable cases I have found that the operation may be relied upon to remove pyloric stricture. With regard, however, to my earlier statement that the stricture will not recur, increased experience has taught me that it was too optimistic; it is not invariably true. It will now be generally admitted that no known treatment will prevent the formation of fresh gastric ulcers and that the scar of the old ulcer or its neighbourhood is a favourite site of recurrence. There is no limit to the contraction of a healing ulcer and the largest pylorus may be closed by it.

The cases suitable for pyloroplasty, as I have previously frequently pointed out, are those with a history of long-standing stomach trouble, foul abundant vomiting towards night, thin patients with dilated stomachs and with a palpable moveable nodule in the pylorus. No other operation, in my opinion, is justified in these cases. They have much diminished in frequency, however, of late years; probably for the same reason as huge ovarian tumours have done the same—viz, that it is so easy to recognise them that they are "worked out."

The brilliant results of gastro-enterostomy obtained by Mayo Robson, Moynihan, and others in the treatment of gastric ulcers have caused quite a boom in this operation, and it seems to be almost as much in fashion to undergo a gastro-enterostomy as to have an appendix removed. But is it not time to call a halt? It takes time to find that there may be objections to new operations. It took ten years for surgeons to discover that myxœdema might follow removal of the thyroid gland. It has taken longer to discover that every diseased ovary does not require removal and that an operation upon it may leave a "cure" worse than the disease. The appendix, too, since Sir William Macewen came to its defence a short time ago, is no longer to be condemned universally as a structure mischievous and useless. (The first and incomplete gall-stone operations occasionally led to the escape of all or a greater part of the bile through an external biliary fistula and this result was said to be attended by no evil result. Where are these patients now? So far as I know none of them survived for ten years.) Is it, then, probable that such a revolution of the chemical and physical processes of digestion as is involved in a successful gastro-enterostomy is likely to be followed by no evils? I do not think that any first-class insurance office would accept at ordinary rates the life of any patient, however apparently well, after this operation. Personally I restrict its use to cases of serious gastric ulceration which have resisted an honest trial of ordinary measures and then I undertake it with a feeling that I should like to know a great deal more than I do of the after-history of patients who were operated upon five years ago.

I have already published in THE LANCET[1] and the *British Medical Journal*[2] the histories of the first 20 consecutive cases on which I had performed the operation of pyloroplasty and the after-history of these cases up to date. All of these patients recovered from the operation, as indeed did the first 23 on whom I operated, and it seemed to me to be a matter of some surgical importance and interest to give a further account of the 20 patients whose history has already been recorded

For the following notes and abstracts I am indebted to the surgical registrar of the Royal Infirmary, Newcastle, Mr. G. Grey Turner, and the indebtedness is not a small one, for the difficulty of tracing some patients is very great. Of the 20 patients one cannot be found and two are dead. These deaths were both referred to in the report in the *British Medical Journal* above referred to. One (Case 4 in the old lists), a woman, aged 59 years, died 18 months after the operation from cancer of the pylorus (a malignant stricture having been mistaken for a simple one); the other (Case 8 in THE LANCET and Case 7 in the *British Medical Journal*) died from phthisis pulmonalis two years and four months after the operation. In this case there had been no recurrence of stomach symptoms when she died.

There remain 17 cases, of the after-histories of which, varying in length from 10 years to five years and three months, I am able to give the following brief particulars. In three the symptoms have recurred, necessitating a further operation. In two of these cases (Nos. 7 and 9) recurrence was due to stricture; in the third (No. 16) the patient has complained more or less ever since her first operation and it is to be observed that it was then specially noted that there was no organic stricture. She has always looked healthy and well in spite of her stomach complaints.

---

[1] THE LANCET, Feb 26th, 1898, p 561.
[2] Brit. Med. Jour., Oct. 19th, 1901.

At the second operation the pylorus easily admitted three fingers. Of the remaining 14 patients, in eight the result may be said to be perfect; in six symptoms more or less troublesome are complained of. On critical examination of these six cases we find that in one (No. 6) no definite organic obstruction was found at the pylorus and that in spite of some trouble (probably of alcoholic origin) the patient has gained weight. In one (No. 8) the patient occasionally vomits but her health is better than before and she is still gaining weight. In one (No. 10) the symptoms are slight and the gain in weight is maintained. In one (No. 12) the symptoms are also slight but the patient has lost weight during the last three years. In one (No. 13) the only complaint is of slight bilious attacks. In one (No. 14) the miserable condition of the patient before operation has been converted into one of comparative comfort.

Newcastle-on-Tyne.

GENERAL GONOCOCCAL INFECTION.

By W. H. WYNN, M.D., B.Sc. Lond., M.Sc., B.Ch. Birm.,
CASUALTY ASSISTANT PHYSICIAN, LATE PATHOLOGIST, GENERAL HOSPITAL, BIRMINGHAM.

To the original idea of gonorrhœa as a purely local disease with acute manifestations and possible chronic complications also of a local character, is now being added that of a general malady, sometimes having an acute septicæmic or pyæmic character, at others producing important inflammatory lesions in many different tissues. A review of the literature shows that practically no tissue can claim immunity from attack; endocarditis, pleurisy, arthritis, meningitis, neuritis, and myositis, inflammations of bone, the eye, the nose, and the skin have all been attributed to this infection. In this gonorrhœa seems to me to show a great family resemblance to such diseases as pneumonia, acute rheumatism, and cerebro-spinal fever, in all of which a diplococcus has been more or less conclusively proved to be the etiological factor. In each case opinion has passed with the growth of bacteriological knowledge from the idea of a local condition to that of a systemic malady. Scarlet fever also has a great resemblance to the members of this group, and although it is never safe to prophesy in pathology, yet one cannot help wondering whether the organism of this disease too will not also prove to be a diplococcus. In each case, although the germ has a different seat of election, the disease often becomes generalised and produces a septicæmia or lesions of various organs and in particular of the serous surfaces (e.g., pericarditis, endocarditis, pleurisy, peritonitis, meningitis, and arthritis). All have in common a marked leucocytosis, and various affections of the skin, the nerves, and the eyes. It is also interesting to note that an attack of one of these diseases appears to predispose to the others. The association of pneumonia with rheumatism, scarlet fever, and cerebro-spinal fever, and of rheumatism with scarlet fever is well known. Rheumatic subjects also seem to suffer severely from gonorrhœa and are difficult to treat.

I had the opportunity a few months ago of examining three cases of gonococcal pyæmia. In one the condition was diagnosed and conclusively demonstrated during life by obtaining the gonococcus in pure culture from the blood. In the other two pyæmia of obscure causation was present and post mortem the only source found was in connexion with a gonorrhœal urethritis; in one of these the gonococcus was cultivated from the blood immediately after death, and in both the organism was demonstrated in the urethral pus and that of various lesions.

Case 1.—A male, aged 19 years, was admitted into the General Hospital, Birmingham, on March 30th, 1904, under the care of Mr. Gilbert Barling. The patient had been ill for five weeks before admission with an abscess over the right hip; during this time he had become very weak, rapidly lost weight, and had remained in bed. On admission he was extremely emaciated and slightly delirious. There was considerable swelling around the left knee and the joint itself was painful and fluctuating. There were also large painful fluctuating swellings over the left calf, the right hip, and the right calf. He complained of scalding on passing urine and there was a moderate muco-purulent urethral discharge. The probable date of infection could not be ascertained, as the pati denied the existence of gonorrhœa even when it was c clusively established by bacteriological examination of urethral pus. The temperature was 99·7° F. and the pr was 144, regular but of low tension. The respirations were and there was considerable bronchitis with abundant mu purulent sputum. The lungs were everywhere resonant on cussion and auscultation showed only the presence of coa and fine rhonchi. The apex beat of the heart was in the fi space in the nipple line; the superficial dulness showed sli extension upwards and to the right. A soft systolic murn was heard at the apex; it was badly conducted towa the axilla and was regarded as functional. A functio pulmonary systolic murmur was also present. Mr. Barli regarded the case as one of general gonococcal infection a requested me to make a bacteriological examination of blood. This was done on April 1st. Blood was taken fr the left median basilic vein in a sterile hypodermic syri and added to sloped agar tubes and also to a tube of mel agar at 40°C. which was afterwards plated. At the sa time Mr. Barling aspirated the left knee, drawing off seve ounces of turbid fluid. Incisions were made into b calves and over the hip, a large quantity of thick yellow pus being evacuated. Films on cover slips and cultures simple and blood agar and in broth were made from t pus and the fluid from the knee. Colonies were visil on the cultures from the blood in 24 hours; in 48 ho they appeared as small round semi-transparent discs with slightly undulated margin. Microscopically these were se to consist of diplococci in pure culture resembling a giving all the tests for gonococci. The films from the fl taken from the knee showed gonococci in large numb both extra- and intra-cellular, the former being oft arranged in large clumps; the extracellular germs were numerous as the intracellular ones. The films from the p showed gonococci similarly arranged but numerous sh bacilli were also present. The tubes of plain agar inoculat with the fluid from the knee gave no growth but the blo agar tubes showed gonococci in pure culture. The pus ga a vigorous growth of bacillus coli in pure culture on t simple agar but mixed growths of bacilli coli and gonococ on the blood agar, the former predominating and so overgrowing the latter.

The patient's condition improved for a time; the kn became free from fluid but remained tender and there w much discharge from the abscesses. On April 3rd t urethral discharge was again examined and typical gon cocci in large numbers were found. No effusion appeared any of the other joints. On the 14th the knee was aga much swollen and two ounces of turbid yellowish fluid we evacuated. This fluid gave the same bacteriological resul as before. The systolic murmur at the apex was mo pronounced but still not definitely organic. On the 16 the knee was still much swollen and the left ankle and wri became affected. A diffuse patch, swollen and tender, al appeared just below the margin of the ribs on the right sid On the 21st the knee was opened by incision and drained; contained several ounces of pus.

The temperature throughout was irregular and showe evening rises to 101° and 102°. At first it was intermitte but later became remittent, the morning temperature bein always above 99°. The pulse varied from 130 to 160 an was soft and feeble. The respirations averaged about 3 By April 21st the patient had become still more emaciated weak, and delirious. The apex beat of the heart was half a inch outside the nipple line and the dulness had increased t the right. Loud rhonchi were heard over both lungs an there was diminished resonance at both bases with fin crepitations. On the 24th he became unconscious an died.

Necropsy.—A post-mortem examination was performed th next day. The body was extremely emaciated and showe a bedsore over the left scapula. The heart weighe 11½ ounces and there was considerable dilatation of both ventricles. The myocardium was pale and showed cloud swelling. The endocardium was blood stained; there wer no vegetations but the edges of the mitral valve were cloud and opaque, suggesting early endocarditis. The right lung weighed 12 ounces and the left weighed 19 ounces. The left pleura was adherent at the base and there was slight exces of fluid in both pleural sacs. There were large areas of collapse in the right lung and the bronchi showed some dilatation. The lower lobe of the left lung contained considerably dilated bronchi forming tubal cavities with thick

muco purulent contents
dilated bronchi The h
gested and œdematous
and the mucous membrane was catarrhal, the intestines were normal The liver was enlarged, weighed 75 ounces and showed marked cloudy swelling with recent venous congestion The right kidney weighed nine ounces, there was considerable dilatation of the pelvis and its calyces The kidney substance was pale and showed cloudy swelling with commencing fatty degeneration The left kidney also showed some dilatation of the pelvis, neither contained any pus The spleen was soft and almost diffluent The bladder was slightly dilated and showed general catarrhal inflammation Pus could be squeezed out of the vesiculæ seminales The prostate and testicles were healthy to the naked eye The urethra showed an acute purulent urethritis Films were made from the pus in the urethra, the vesiculæ seminales the knee joint and the abscesses in the legs In all the gonococcus could be demonstrated Smears from the mitral valve showed typical gonococci but cultures from the valve remained sterile

CASE 2 —*A man, aged 24 years* was admitted to hospital under Mr Barling on April 8th 1904 complaining of pain in the back *This* had been *first* noticed six months previously after an attack of hæmaturia The pain was at first most marked on the left side but latterly it had been on the right There had been four attacks of hæmaturia before admission *the first two* lasting for about nine days There was slight pain at the commencement of micturition and during the periods of hæmaturia the patient had noticed that the flow of urine would sometimes stop and then begin again suddenly accompanied by blood towards the end of the act He always lay *on the the right side, attempts to lie on the left* causing pain On examination there were slight pain and tenderness *in the region of the* left kidney on palpation but no tumour was felt, the right side was free from tenderness on manipulation *The* temperature on admisison was normal The urine

stone but was found with its pelvis and ureter quite normal A cystoscopic examination of the bladder at the same time showed a small nodule of about the size of a pea just behind the inter ureteral bar A second examination with the cystoscope was made on the 27th and a small translucent papillomatous mass was observed at the base it was doubtful whether this was growth or merely stringy mucus attached to the bladder wall On May 13th a small clot was seen at the base of the bladder A suprapubic cystotomy was then performed and a small circular ulcer about one sixth of an inch in diameter was found and scraped There was no evidence as to its cause The temperature from May 6th to 19th showed evening rises to 100° F with morning remissions, it then remained normal for a week but on the 25th rose quickly to 103 5°, the pulse being then 136 and the respirations 28 The temperature then continued very irregular and of a pyæmic character A few crepitations were heard at both lung bases and an apical systolic murmur was present Later dulness appeared at both bases with bronchial breathing and crepitations The spleen was palpable The suprapubic wound remained quite healthy The patient died on June 13th

Necropsy — A post mortem examination was held 16 hours later The body was considerably emaciated Rigor mortis was present in the legs only and post mortem lividity was slight The suprapubic wound was quite healthy On cutting through the chest wall numerous small subcutaneous and intramuscular abscesses were found The pericardium was normal, the heart weighed 11½ ounces There was a row of small warty recent vegetations on the margin of the auricular surface of the mitral valve and a few similar ones on the tricuspid valve The aortic and pulmonary valves were healthy The heart muscle was pale and showed cloudy swelling Both ventricles were moderately dilated The lungs were very congested and contained small patches of hypostatic pneumonia In the upper lobe of the left lung there were two small septic infarcts The liver was slightly enlarged and fatty Both kidneys were in a condition of suppurative nephritis the right contained several abscesses opening into the pelvis, and the left a few miliary abscesses The spleen was enlarged, it weighed ten ounces and contained a small white infarct at its upper end The bladder was of small size with a moderately hypertrophied wall There were a few small red velvety patches
n The posterior wall showed
and the mucous membrane
the base of the bladder in
the *connective tissue* of the pelvic wall there were two large abscess cavities These were burrowing between the bladder and the rectum and around the neck of the bladder *They* were entirely subperitoneal and had no connexion with the operation wound The se
communicated with the
brain were cloudy and the
in excess, these appearances resembled an early meningitis The brain substance was soft and œdematous but contained no abscesses Films were made from the pus *from the* urethra the vesiculæ seminales the pelvic abscesses and the abscesses in the chest wall All *these showed numerous* gonococci with bacilli and staphylococci No gonococci were found in films from the heart valves, the lungs the spleen the kidneys or the meninges but only bacilli and staphylococci Cultures were made on blood agar, *plain* agar and in broth The two latter media gave only mixed growths of bacillus coli and staphylococcus aureus A feeble growth of the gonococcus was obtained on the blood agar from the pus in the vesiculæ seminales and the pelvic abscesses but not from that in other situations In both cases the growth was mixed with colonies of bacillus coli and staphylococci

CASE 3 —A male aged 19 years was admitted under the care of Dr R M Simon on March 25th 1904 His friends gave the history that he was well until March 20th when he complained of pain in the back which was regarded as lumbago He went to work in spite of the pain and of feeling unwell but on the 22nd was obliged to stay in bed The following day he complained of cough, dryness of the throat, and of feeling 'stupid On admission he was delirious and unable to answer questions There was some slight twitching of the facial muscles and of the hands The temperature was 105° F the pulse was 124 soft, and very dicrotic The tongue was covered with a dirty brown fur Nothing abnormal was detected in the chest The abdomen was slightly distended but not tender There was retention of urine, specimens obtained by catherisation contained much albumin a few granular casts, 4 per cent of urea with a specific gravity of 1020 The spleen was just palpable A chronic urethritis with a gleety discharge was also present Enteric fever was at first suspected but there was no rash and the serum reaction gave a negative result On the 28th a bacteriological examination of the blood was made also with a negative result He became worse and the delirium increased The bowels were constipated and the stools were of a light yellow colour On the 30th he was in a state of stupor The hands were occasionally moved to the head as though he had pain there The neck was somewhat rigid and he resisted movements of the head The pupils were rather dilated but there was no muscular twitching Some dulness appeared at the lung bases with crepitations Respirations were 68 and the temperature rose to 105° and finally to 106° just before death which occurred on the evening of the 30th

Necr the next
day with
recent The
heart weighed [illegible] ed one ounce of clear fluid The myocardium showed marked cloudy swelling and the right side of the heart was dilated and contained mixed post mortem clot The valves were healthy and showed no signs of endocarditis The lungs weighed 20 and 24 ounces The pleuræ were non adherent and the cavities contained a little turbid fluid Both lungs showed scattered miliary abscesses over their surfaces The right lung was emphysematous and intensely congested Near the apex of the lower lobe was a septic infarct The lower lobe of the left lung felt shotty and contained numerous septic foci surrounded by small patches of pneumonia the rest of the lung was emphysematous The bronchi and trachea showed vascular injection The peritoneum was normal the stomach showed some catarrhal inflammation The Peyer s patches towards the lower end of the ileum were enlarged and the large intestine was distended with gas The liver weighed 74 ounces and showed cloudy swelling The right kidney weighed seven and a half ounces, it substance was pale with injected vessels and it contained numerous scattered miliary abscesses The left kidney weighed four and a half ounces and formed a large sac of the size of a fœtal

head from distension of the pelvis. The ureter entered the pelvis by a narrow opening just admitting a No. 8 catheter; the entrance was abrupt and towards the upper end of the pelvis; it had evidently acted as an obstruction and produced the hydronephrosis. The kidney substance was reduced to a mere shell a quarter of an inch thick; it was pale and injected but not fibrosed. The spleen weighed ten ounces; it was soft, purplish-red, but contained no abscesses. The bladder was distended and thin-walled; the mucous membrane was normal. The urethra contained a little thin pus from chronic urethritis and a small abscess was found in the prostate; the seminal vesicles also contained a little pus. There was no urethral stricture. The brain weighed 53 ounces. The subarachnoid fluid was in excess and turbid but there was no pus in the meninges or brain substance. The middle ears, nose, mouth, and frontal and other accessory cranial cavities were all examined but were found to be normal.

A bacteriological examination of the heart blood was made one hour after death by sterilising the skin and withdrawing blood from the heart with a sterile hypodermic needle. The blood was poured on to the surface of sloped agar and after 36 hours showed typical colonies of gonococci in pure culture. The blood from the spleen was examined in the same way but gave negative results. Films and cultures on blood agar were made from the urethra, the prostate, the seminal vesicles, the kidney, and the lungs. All the films showed typical gonococci together with short bacilli and staphylococci. In the urethra the organisms were nearly all intracellular but from the other situations the extracellular ones were as numerous as the intracellular. No colonies of gonococci were obtained from the cultures from the urethra, but a good growth was obtained from the prostatic abscess and a feeble growth from the lungs and kidneys; in all cases except from the blood immediately after death there were also abundant colonies of bacillus coli and staphylococcus albus.

In all three cases the primary seat of infection was the urethra. The date of infection was not determined but in Case 1 the urethritis was in an acute stage, in the other two it was chronic. The vesiculæ seminales were affected in all three cases and possibly the general invasion took place from them rather than from the urethra itself. In Case 3 the prostatic abscess was also a possible site of origin. I regard these secondary foci as more important than the urethritis, because the pus from them showed more numerous extracellular, and, therefore, presumably more active, gonococci than did that from the urethra. In the second case it is possible that the disturbances to the base of the bladder from the operation was the exciting cause of the general infection by lowering the resistance of the part and causing the spread from the seminal vesicles to the pelvic connective tissue. General gonococcal infection is much more common in males than females and the primary seat is almost always the urethra or metastases secondary to this in the neighbourhood. It is uncommon in females although it may follow primary infection as in males. Hamilton[1] suggests that greater resistance is offered to the general spread of infection in the uterus, the adnexa, and the pelvic peritoneum. But I would suggest that the difference is chiefly accounted for by the greater length of the male urethra and the presence of numerous diverticula and sinuses which provide an excellent breeding ground for the germs. Gonorrhœal ophthalmia may also give rise to general infection and many cases of arthritis in infants and even of pyæmia have been described.

The subcutaneous abscesses found in Cases 1 and 2 are among the rarest complications of gonorrhœa. It was once believed that pus was rarely if ever produced by the gonococcus alone but only by the addition of other organisms. In Case 1 although the gonococcus alone was found in the blood and the turbid knee fluid, yet the purulent foci also contained bacilli coli. In Cases 2 and 3 bacilli coli and staphylococci were also found in the pus, so that these cases would seem to favour the original view. Many cases, however, have been described in which pure cultures of the gonococcus were obtained from pus. Inoculation experiments have only given negative results. Wertheim[2] in 1892 introduced cultures under his own skin; a circumscribed inflammation without suppuration only resulted. Steinschneider[3] in 1893, in repeating the experiment, obtained only negative results. Putting on one side the peri- and para-urethral abscesses and inguinal buboes where the infection can spread by direct extension or lymphatic paths there are still some relatively rare cases resembling the three I have reported in which suppuration has developed far from the urethra and in some of these the gonococcus has been found alone. In some of these cases abscesses have developed at places previously bruised or damaged. In a case recorded by Cassel[4] in 1903 an abscess in the back containing a pure growth of the gonococcus followed purulent gonorrhœal ophthalmia in an infant.

Case 2 showed a condition which has generally been regarded as occurring only in women—pelvic cellulitis. In this case the peritoneum was not involved, but Battez[5] has collected 30 cases of gonorrhœal pelvic peritonitis in the male following secondary infection of the bladder, the prostate, or the seminal vesicles. Case 3 showed a typical pyæmia with abscesses, especially in the lungs and the kidneys. I have not discovered a case previously in which gonococci have been described in the lungs. The pus in the lungs and kidneys showed a mixed infection and no case has as yet been described in which the infection of the kidney was proved to be due to the gonococcus alone.

Recent endocarditis was present in the two first cases which had evidently developed during the course of the illness. In Case 1 it was quite early and was only revealed by slight cloudiness and opacity of the edges of the mitral valve; cultures from it were negative but smear preparations showed gonococci alone present. In the second case small warty vegetations were present but cultures and films showed no gonococci but only bacilli coli and staphylococci. The former I regard as an undoubted gonorrhœal endocarditis but the evidence for the latter is inconclusive; gonococci may have been present in the early stages and begun the process, these organisms later disappearing and being replaced by a mixed infection. This is in harmony with what we know of gonorrhœal arthritis in which gonococci are usually only present in the quite early stages.

Enough evidence has now accumulated to show that the lesions and symptoms of the general infection depend mainly upon three factors—viz., (1) direct infection with the gonococcus itself; (2) an absorption of a toxin, gonotoxin; and (3) mixed infection with other germs. There is now definite evidence that gonococci can circulate in the blood and produce the lesions found in the various organs; there is a true invasion by the organisms. As early as 1878 Bouchard and Capitan had positive results from examination of the blood; later Petroni, in 1883, and Julien, in 1886, obtained similar results. These early observers have been followed by many others, especially on the continent. In England the condition appears to have received but little attention and but few cases are described in which pure cultures have been obtained from the blood. On the other hand, some observers have met with uniformly negative results. Trapeznikoff,[6] in 1892, did not succeed with the blood in 32 cases. It may be that sufficient blood was not taken, but it is also probable that the organisms do not remain long in the blood but become localised in the organs and tissues. Bressel[7] in a case of pneumonia supervening on the decline of a gonorrhœa obtained a pure culture from the blood on the fourth day but failed later.

De Christmas[8] and Wassermann[9] have separately studied the toxins; the latter obtained them by growing the gonococcus on a special medium. To these toxins he attributes the general symptoms. Experimental inoculation resulted in a very lively reaction at the site of injection with fever, malaise, muscular and articular pains, and loss of weight. This general intoxication had already been hinted at by Pidoux as early as 1866, who had called attention to the disproportionate alterations in the face and general health of patients suffering from recent gonorrhœa, their pallor, slight rapid wasting, discolouration of the skin, and fever. Padrez,[10] in 1885, and Drobney, in 1898, observed that in those cases in which the gonococci were found within the pus cells the disease ran a milder course than when the organisms were free. They claim that the toxin inhibits phagocytic action and so affords an opportunity for general invasion My own observations would support this, for, as I have stated above, the more active the lesion the more extra cellular were the organisms On the other hand, I think that in many cases a mixed infection with other pyogenic germs plays an important part The gonococcus is rarely isolated in pure culture and if found at all it is usually only during the earlier stages It would be surprising if mixed infection did not occur, considering the ease with which pyogenic germs could invade the body through the primary gonorrhœal lesions The bacillus coli seems to be the organism most usually found, which is in correspondence with the fact that it is the commonest organism found in cystitis and other diseases of the urinary passages When found in lesions after death little importance can be placed in its presence as it is found so often in a variety of diseases from "agonal' or post mortem invasion But whatever organism be found in association with the gonococcus its action is, I believe, purely secondary It completes the work [illegible] re delicate [illegible] septicæmia [illegible] due to the [illegible] the possible gonorrhœal origin of pyæmia, but also because these cases do not often occur in connexion with an acute gonorrhœa but from secondary foci in the prostate or seminal vesicles which are often latent Gonorrhœa may be denied by the patient and the chronic gleety discharge overlooked by his attendant Ullmann[11] reported five cases of fatal gonorrhœal pyæmia, in four of which the necropsy showed the point of origin to be a prostatic abscess In three of the cases the clinical diagnoses were typhoid fever, malignant tumour of the prostate, and purulent cystitis and septicæmia of doubtful origin Such cases show the need for the routine examination of the urinary organs and especially of the prostate in all cases of pyæmia of obscure causation just as the middle ear is now always examined in similar cases Gonorrhœal infection has no special clinical features which differentiate it from other pyæmias and a positive diagnosis can only be made by a bacteriological examination of the blood or of any accessible lesions

Technique —For the examination of the blood stained films are not sufficient, cultures must be made upon suitable media The essential constituent of these media seems to be blood serum or similar albuminous material from the animal body Practically blood agar is the most convenient means of cultivating the gonococcus At least one cubic centimetre of blood should be taken with a sterilised hypodermic syringe from one of the large veins of the elbow No antiseptic must be used in sterilising the skin, simple cleansing with spirit and ether is sufficient for this purpose The blood should then be poured on to the surface of one or two agar "slopes,' the tubes being kept slightly inclined until the blood has coagulated A relatively large quantity of blood must be used as it is necessary to have, as Harris[12] has shown, abundant albuminous material present Another method is to mix the blood with one or two tubes of melted agar kept at a temperature of 40° C, the mixture then being slanted or plated in a Petri s dish The former method I think is preferable, as a freer access of oxygen is obtained than by mixing the blood with the agar I have failed with the latter method when the former has been quite successful For the same reason fluid media are unsuitable as the blood clots and falls to the bottom For cultivation from pus or lesions of the organs blood agar can also be used The blood must be liberally distributed over the surface of agar "slants and not simply a few drops smeared over it Serum agar is also an excellent medium one part of *blood serum being* used to *two or three* parts of agar Young[13] has used hydrocele fluid successfully, while Wright[14] ad [illegible] by mixing under asep [illegible] a temperature of 40° [illegible] a sterile mixture of [illegible] an urine (one part) I have had no personal experience of this last method The identification of the gonococcus is usually said to depend upon three characteristics (1) characteristic colonies are produced upon certain media, (2) it will not grow upon simple agar or in broth, and (3) it is not stained by Gram's method Of these, only the first is certain The colonies appear after 24 hours as minute, greyish, semi-translucent points In 48 hours they are well developed and under a low magnifying power each is seen to be circular with thin, translucent, sharply defined margins The margins are slightly undulated and in older colonies may send out slight processes The colonies become brownish, denser, and granular towards the centre Wildbolz[15] has succeeded in growing the gonococcus upon agar after cultivating on serum agar for four or five generations sometimes earlier This test cannot therefore be relied upon especially as the diplococcus meningitidis is also difficult to grow upon agar There are also fallacies in the test by Gram s method Colonies not more than 48 hours old must be used as other cocci usually staining by Gram's method may be decolourised in older cultures Mallory and [illegible] coccus in an arthritis [illegible] origin which in films [illegible] ultures proved that it [illegible] g suspected films by Gram s method it is useful to place a few staphylococci in one corner of the slide for a comparison Practically, then, most reliance must be placed on the appearance of the colonies grown on blood or serum agar and if these colonies are composed of cocci of characteristic appearance and decolourised by Gram s method the identification is certain

When in cases of obscure pyæmia the blood has been examined during life with negative results I would suggest that the blood from the heart and spleen should be examined as soon as possible after death Permission for this could often be obtained when an ordinary post mortem examination would not be allowed It is also useful when a necropsy is obtained as bacteriological examinations of the organs and blood 24 hours after death are made untrustworthy by the invasion of other organisms, especially from the intestines

I must in conclusion, express my indebtedness to Mr Barling and Dr Simon for their kind permission to make use of their cases

Birmingham

A HAT PIN 4¾ INCHES LONG IN THE ŒSOPHAGUS PRODUCING A FALSE ANEURYSM OF THE SUPERIOR MESENTERIC ARTERY

By H D ROLLESTON, M D CANTAB, F R C P LOND,
PHYSICIAN TO ST GEORGE'S HOSPITAL,

AND

F R C WHIPHAM M B OXON, M R C P LOND,
ASSISTANT CURATOR OF THE MUSEUM AT ST GEORGE'S HOSPITAL
PHYSICIAN TO OUT PATIENTS AT THE EVELINA HOSPITAL FOR SICK CHILDREN

A FEMALE child three years of age, who had been ailing for two months, was admitted into St George's Hospital on June 25th, 1904, with wasting, anæmia, rickets, inability to sit up, and a distended abdomen A diagnosis of tuberculous peritonitis was made and on July 6th the patient was transferred for further treatment to the Atkinson Morley Convalescent Hospital at Wimbledon While there the child did not improve, she lost weight, developed retraction of the head, and on August 18th vomited *some* fresh blood clot of the size of a grape and on two subsequent occasions brought up some dark discoloured blood She was re admitted to St George's Hospital on August 24th looking like a most advanced case of tuberculous peritonitis, and she continued to get worse On the 30th she vomited a clot of fresh blood of about the size of a walnut and becoming very collapsed, died at 8 P M

The diagnosis of tuberculous peritonitis rested on the swollen abdomen, the diarrhœa, the enlargement of the spleen and liver, and the wasting, while crackles at the apices of the lungs and retraction of the head suggested more widespread tuberculosis Hæmatemesis in tuberculous peritonitis is such an unusual event that a necropsy was highly desirable, as it was thought that it might disclose some rare condition, such as tuberculous ulceration of the stomach or of the œsophagus.

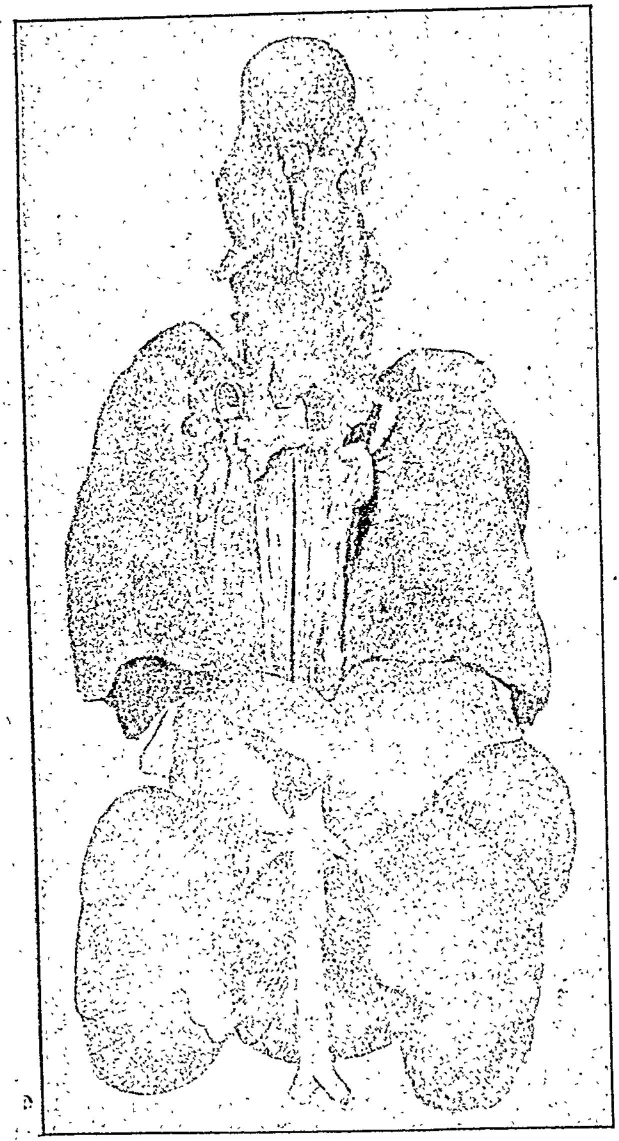
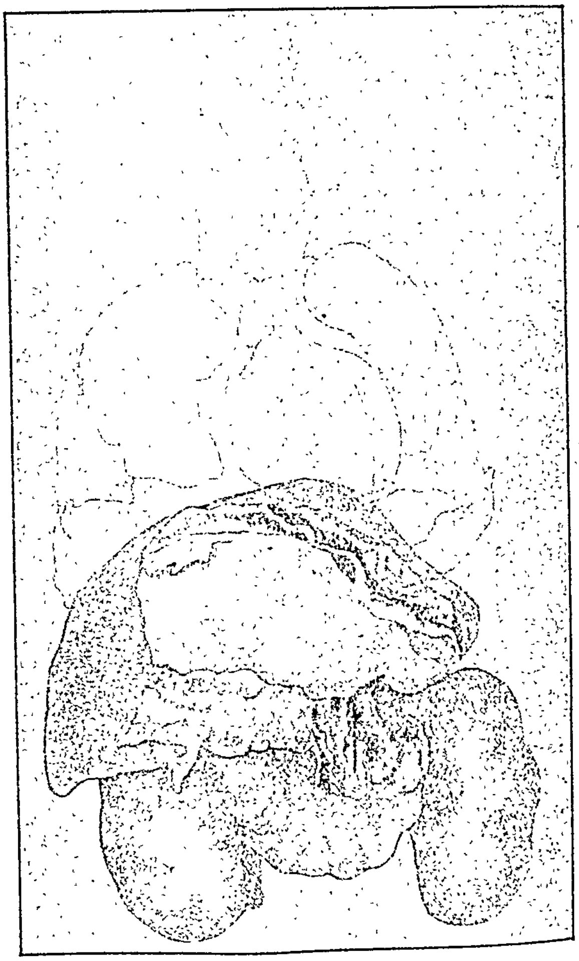
Necropsy.—The body was thin and showed marked signs of rickets. There was no external wound or lesion of the skin except some small quite superficial scars over the sacrum, probably the result of pressure sores. The œsophagus (Fig. 1) contained part of a long black pin, resembling a hat pin, of which two and a half inches of the pointed end projected upwards through a small hole in the wall of the gullet on the right side just above the level of the diaphragm. The pin, which was four and three-quarter inches long and partially eroded, had evidently been swallowed head downwards. The actual head of the pin, which was missing and could not be found, had probably become detached soon after swallowing and had been voided *per vias naturales*. The shaft was slightly bent with the concavity forwards and the head end, which was very sharp but not shaped to a point like the other, had penetrated the œsophageal wall at the point described and passing in front of the aorta had pierced the diaphragm and had travelled downwards behind the stomach without injuring it through the extreme posterior portion of the pancreas; thence it turned a little forwards to a point immediately above the duodenum where it had perforated the upper wall of the superior mesenteric artery (Fig. 2). Between the pancreas and the duodenum there was a small false aneurysm filled with blood clot and of the size of a cherry in the root of the mesentery. The track of the pin above this was also filled with blood. The superior mesenteric vein, which lay to the right and slightly in front of the aneurysm, was partially thrombosed with ante-mortem clot. The point or upper end of the pin lay in the œsophagus opposite the apices of the lower lobes of the lungs posteriorly. At this level there was a small suppurating lymphatic gland behind the œsophagus with a small abscess on either side of it; that on the left was the larger of the two and had invaded to a slight extent the lower lobe of the lung, causing several small foci of suppuration around. A direct communication was found between the œsophagus and the abscess on the right and a similar condition had possibly existed on the left side. Unfortunately in removing the contents of the thorax the œsophagus was torn in this position, so that this point could not be established; at all events the wall was much softened and very friable. From the abscess cavity on the right a sinus, large enough to admit the extreme tip of the little finger, passed upwards to the first dorsal vertebra. This sinus, which was apparently of some little standing, contained small flakes of necrosed bone. The body of the first dorsal vertebra was slightly necrosed and the bodies of the next four dorsal vertebræ were extensively carious, those of the third, fourth, and fifth having almost entirely disappeared; the process stopped at the upper part of the body of the sixth. The second to the sixth costal articulations on the right side and the third to the sixth on the left were also extensively eroded. There was recent fibrinous pleurisy over the posterior

FIG. 1.



Œsophagus opened from the back showing the sharp pointed end of the hat pin pointing upwards from the spot where it penetrated the œsophageal wall. To the right of the œsophagus in this situation a suppurating gland is seen.

FIG. 2.



Shows the end of the pin penetrating the superior mesenteric artery.

surfaces of both lungs with recent adhesions on the right. The lower lobe of the right lung showed some collapse. No sign of tubercle was visible in either. The pericardium contained an excess of serous fluid. The heart and other viscera were normal and presented no evidence of tuberculosis. The stomach was filled with blood clot and the intestines contained a considerable quantity. There was no ulceration or other lesion of the stomach or intestines, so that it seems probable that the blood had tracked up from the aneurysm along the course of the pin and entered the alimentary canal at the perforation of the œsophagus. There was no sign of injury, either recent or old, on the palate or in the pharynx. The brain was normal and there was no meningitis.

The lesions of the spinal column gave every appearance of being of lo[illegible] infiltration c[illegible] the sinus on [illegible] occurred me[illegible] *happened if the condition was due solely to perforation* by the point of the pin. The clinical history that blood had only been vomited during the last two weeks and the fact that only the upper wall of the superior mesenteric artery had been pierced indicate that the pin had only recently reached the position in which it was found post mortem. Before this it must have been above the level of the suppuration and therefore not the cause of it. Tuberculous osteitis of the dorsal spine and the suppuration in the adjacent mediastinal gland were therefore probably antecedent to, and independent of, the perforation of the neighbouring part of the œsophagus by the pin. In all probability the point of the pin perforated the wall of the œsophagus, softened by suppuration from the spine, shortly before death.

As has been pointed out, the presence of the pin in the œsophagus was not suspected during life. It, however, appeared at the inquest that the mother believed that the child had swallowed a pin and indeed had mentioned her belief at another hospital, but not meeting with much sympathy there had refrained from saying anything about it at St. George's Hospital. The pin was evidently swallowed head downwards and its rounded end and the flexibility of its shaft must have enabled it to glide along the posterior wall of the pharynx into the œsophagus. In a very similar case recorded by Holding[1] a female child aged 20 months probably fell on the head-end of a hat pin which passed into the stomach and after being localised by skiagraphy was successfully removed by gastrostomy. It is noteworthy that in our case the pin had been in the œsophagus for over two months.

It may be added that during the last few years there have been at least ten other cases of foreign bodies, other than food, impacted in the œsophagus at St. George's Hospital—viz., four cases of tooth plates, of which three terminated fatally, one case of a pin which perforated the aorta and proved fatal (recorded by Sir Isambard Owen),[2] three cases of halfpennies, one case of a whistle, and one of a brooch, all swallowed by children and all treated successfully. For the two illustrations we are indebted to the skill of Mr. Lawrence Jones.

MANDIBULAR PROCESSES ASSOCIATED WITH DOUBLE HARE-LIP AND CLEFT PALATE.

By WALTER LEY WOOLLCOMBE, M.R.C.S. Eng., F.R.C.S. Edin.,

SURGEON TO THE SOUTH DEVON AND EAST CORNWALL HOSPITAL.

Two children have recently been under my care for double hare-lip and cleft palate both of whom exhibited a peculiar deformity of the lower lip, which has been described and figured by Mr. J. Bland-Sutton[3] and others[4] and attributed by them to imperfect coalescence of the mandibular processes, but which I have never seen before in 18 years of hospital practice nor do many others seem to have described it.

CASE 1.—The patient was a boy, aged three months (sent by Mr. A. E. Gladstone of Newton Ferrers), whose father was born with hare-lip and cleft palate but who had two sisters without this deformity. The father and mother were not related. The boy had a complete cleft of the hard and soft palate and the worst looking hare-lip I have ever seen owing to the fact that the clefts on either side of the premaxilla were very wide and that the latter process was held forward by the vomer so that it stood out three-quarters of an inch in front of the rest of the upper lip. On the lower lip, which was perfect in outline, and at a distance of one centimetre on either side of the mid-line, were two depressions out of each of which protruded a nipple-shaped process about one centimetre in length which is diagrammatically represented in Fig. 1 These processes were capable of a good deal of movement and several times per minute were protruded and retracted in a most uncanny way like feelers. The recesses were always full of mucus. The upper lip was treated by peeling back the periosteum from, and excising three-quarters of an inch of the central part of, the vomer, pressing the premaxilla back into the interval between the separated alveolar borders of the superior maxillæ, suturing it in place after freshening the opposing surfaces, then uniting flaps from the lips on either side, utilising the soft parts covering the premaxilla to fill in the central gap. The lower lip was subsequently treated by excising an elliptical portion of it, including the two recesses and tubercles, going deeply enough to remove all [illegible] em.

FIG. 1.

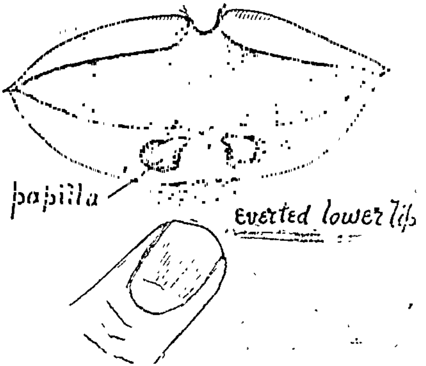


Diagram of the everted lower lip, showing the mandibular processes and recesses.

C[illegible] aged four months (sent [illegible] who came of a healthy [illegible] other member of the [illegible] condition was exactly similar to that in Case 1, except that the recesses and tubercles were much smaller and did not secrete nearly so much mucus.

The facts that these recesses and processes have never been observed apart from double hare-lip—i.e., imperfect coalescence of the naso-frontal and maxillary processes—and also that Feurer once found a similar recess in the upper lip at the junction of these processes make it appear likely that the deformity is in some way connected with the intermandibular fissure, but this reasoning does not seem to me to explain satisfactorily the following points: (1) There are always a pair of recesses and they always seem to be situated at an equal and definite distance from the mid-line (about one centimetre); (2) there is never any irregularity in the line of the lip, which is perfectly united at the mid-line; and (3) the large amount of glandular tissue grouped around the recess.

The excised part of the lower lip bearing the two papilla[illegible] processes was submitted for examination to Dr. Arthur Keith who reported as follows: "Each process is made of three elements: (1) a clump of mucous glands which forms the core: the ducts of these glands open close together near the apex of the process; (2) a layer of muscular tissue continuous with the orbicularis oris which surrounds the

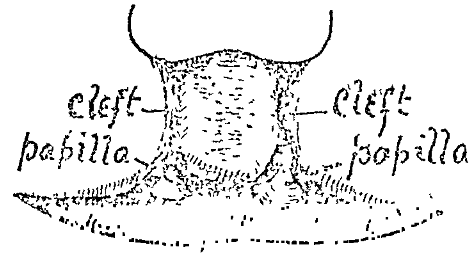
---

[illegible] nbeck's

glandular centre; (3) a covering of mucous membrane continuous with the mucous membrane of the lip. The depression described by Mr. Woollcombe as surrounding each process had become obliterated by the shrinkage caused by the preserving reagent.

Such deformities of the lower lip are very rare; they are always associated with double hare-lip. Comparative anatomy lends no support to any theory that regards these labial processes as atavistic structures. Embryology cannot account for their presence; they occur at some distance from the median line of the lower lip. The explanation of this anomaly given by Dr. E. Hamilton is the most satisfactory.[5] He noted that when the lips were closed the papillæ fitted within the clefts in the upper lip (see Fig. 2). During development the mucous surfaces of the lips are in contact; the developing tissue of the lower lip, lying opposite the clefts in the upper lip, is unrestrained in its growth and tends to fill the opposing gaps in the upper lip. On this interpretation the papillary processes represent attempts on the part of the lower lip to compensate for the defective development on the part of the upper."

FIG. 2.



Illustrating a condition similar to that in Case 1, described by Dr. E. Hamilton.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus Morb.*, lib. iv., Proœmium.

UNIVERSITY COLLEGE HOSPITAL.

A CASE OF SEVERE ULCERATIVE COLITIS; RECOVERY

(Under the care of Dr. F. J. POYNTON.)

FOR the notes of the case we are indebted to Dr. A. J. Blaxland, house physician.

The patient, a man, aged 27 years, was admitted into University College Hospital on August 12th, 1904. The illness had commenced a month before this with severe abdominal pain and diarrhœa. The onset was sudden and in the first 24 hours he had noticed blood in the stools. Previously to the attack of pain the bowels had been loose for a week. The pain and diarrhœa persisted and as many as 20 stools were passed in the day, the great majority of which contained blood.

The condition on admission was extremely grave. The face was pinched and anxious, the eyes were sunken, the extremities were cold, and the voice was husky. The patient was greatly emaciated and over the sacrum there was a small bedsore. It was remarkable that although there was pain in the region of the colon, there was at no time any distension, the abdomen on the contrary being incurved. The temperature was 99·2° F., the respirations were 20, and the pulse was 96 to the minute. The tongue was dry and furred and the mucous membranes were anæmic. Nothing abnormal was discovered on examination of the abdomen but examination of the rectum through a speculum showed a polypoid condition of the mucous membrane and some superficial ulceration. The stools were offensive and were composed almost entirely of blood and mucus. From time to time small sloughs were visible. The blood was sometimes bright red and sometimes darker. During the first three days in the hospital from 17 to 21 stools were passed in the day.

The following treatment was adopted in addition to the most careful and skilful nursing. The patient was placed on a strictly milk diet. Bismuth carbonate in 30-grain doses combined with 15 minims of tincture of opium were given by the mouth every four hours. Rectal injections of a solution of silver nitrate (15 grains to the pint of distilled water) were administered every night. Two pints were injected very slowly through a long soft tube and funnel and when these were returned an enema of sodium chloride solution was given. Although administered with the utmost care these injections caused considerable pain. Progress was immediate. The pain was eased by the opium and the patient gained some rest between the actions of the bowels and more tranquillity throughout the day. In three days the number of motions was reduced to seven in the 24 hours and after a week to five. The mucus in them decreased and the offensive odour was diminished. Blood was still present in every motion but there was a distinct gain in the strength of the patient. The bismuth and opium, too, were exerting a good effect on the diarrhœa. This was shown by the fact that it was thought advisable at the end of the first week to stop the injections for some days. There was then no marked increase of the diarrhœa, although the motions became more offensive and unhealthy. The treatment was with this exception continued for seven weeks and during that time the condition of the patient improved very greatly. By that time the motions were diminished to three per diem and they were beginning to be formed, although even now there was occasionally a considerable amount of blood passed. At this date the discomfort produced by the injections—the patient himself being, as is so often the case with abdominal maladies, inclined to be depressed and unhappy—caused them to be left off again. In less than a week the motions became more unhealthy and contained a quantity of mucus and, what was even more convincing, the patient's face became pinched and drawn; there was also some little pyrexia. Accordingly the injections were resumed every other day and then on Oct. 13th were given every third day. From Oct. 6th to 30th his weight increased from 7 stones 5 pounds to 8 stones 6 pounds. When he left the hospital at the end of the month he was quite convalescent, and after a month at the seaside he returned weighing 9 stones 6 pounds and with the bowels acting naturally once a day.

Remarks by Dr. POYNTON.—This case is sent for publication because the result after the treatment was most striking and most encouraging in a condition that is admittedly one of the greatest gravity. It must be acknowledged that the administration of injections of some bulk in cases of ulceration of the bowel is always an anxious and hazardous undertaking, for it is not possible from clinical evidence to say how deeply one of the ulcers may have extended, but there can be no doubt in this case that a few more days without some improvement would have ended the patient's life. The case was one of an exceedingly severe type and the recovery was more complete than even the most sanguine could have expected.

HARROGATE INFIRMARY.

A CASE OF RUPTURED TUBAL GESTATION; OPERATION; RECOVERY.

(Under the care of Mr. ERNEST SOLLY.)

THE patient was a married woman, aged 38 years, who had had two children (now aged 17 years and four years respectively). The general health had been good and with the exception of a "slight miscarriage" three years after the birth of the first child and a certain amount of leucorrhœal discharge at times ever since—never enough to cause obvious effect upon the health or even to be considered worth noticing—there were no symptoms of disease of the pelvic organs. On Oct. 27th, 1904, the patient thought that she had another "slight miscarriage," as her period was a week or ten days overdue and there was some uterine hæmorrhage, dark in colour and with some clots. There was no pain or other disturbance and the patient kept about doing her housework. On the 30th, about 6 P.M., while pouring out tea, she felt a violent pain in the abdomen, mostly "low down," but also across the epigastric [illegible] She went to bed [illegible] although the former [illegible] doses of morphine a [illegible] All symptoms became [illegible] the next day and about [illegible] asked to see her by Mr. Christian. She was found to be collapsed and almost pulseless but the beats were able to be counted as about 90. The abdomen was distended and tender, especially in the hypogastric region, where there was some dulness. The liver dulness was not affected. Tenderness was certainly more [illegible] gion but as the patient [illegible] morphine it could not [illegible] tances made operation inadvisable in her own house so she was taken in a wheeled ambulance litter to the infirmary and on arrival there received ten minims of liquor strychninæ hypodermically and one ounce of brandy diluted to three ounces into the rectum. Mr. Solly opened the abdomen at about 8 30 P.M. by median incision below the umbilicus. There was free discharge of blood, both liquid and in clots (of the latter a 20-ounce measureful was easily collected), and some shreds of membrane were recognised. About half an inch from the uterine end of the right Fallopian tube was a swelling about one inch in diameter with a ragged rent on its upper surface; inside were some more shreds of fœtal membranes. The sac and the rest of the right Fallopian tube and the ovary were removed after the passing of ligatures of silkworm gut. The abdominal cavity was as far as possible cleansed from clots and blood, sterilised normal saline solution (about four pints) being used for flushing out the abdominal cavity. The peritoneum was closed by a continuous catgut suture, a glass drainage-tube being left leading down to the pelvis, and the external wound was closed by interrupted sutures of silkworm gut. The patient's condition was critical throughout and during the operation about one and a half pints of normal saline solution were introduced under the pectoral fascia. During the night three ounces of saline solution were injected per rectum—at midnight, at 4 A.M., and at 8 A.M., and nutrient enemata alternately with these. These injections were continued alternately during the next 24 hours, after which feeding by the mouth was commenced. Recovery was uninterrupted and uneventful. The glass drainage-tube was removed on the third day and all sutures on the seventh day as the wound healed by first intention. The patient was kept in bed for a month to avoid risk of embolism from detachment of possible clots in the veins but she left the infirmary perfectly well on Dec. 8th and has remained well. Although still pale she is said not to be much paler than before and she is quite able to attend to ordinary household duties.

---

[5] See Ballantyne's Antenatal Pathology, vol. ii., p. 397, 1904.

Remarks by MR. SOLLY.—Successful cases of operation for the above condition, even when the patient has been apparently moribund, are fortunately becoming more frequent than they used to be but I think the case recorded above, in addition to its own points of interest, is worthy of publication as a further encouragement towards radical treatment of such emergencies however hopeless it may seem to expect success.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Some Observations on Pancreatic Secretion in Man.

A LABORATORY meeting of this society was held on Feb. 7th at St. Mary's Hospital Medical School, Dr. A. E. WRIGHT being in the chair.

Mr. W. H. CLAYTON-GREENE (introduced by Dr. WRIGHT) read a paper on Pancreatic Secretion in Man. The paper started with a brief description of a case of carcinoma of the pyloric end of the stomach. The patient, a man, aged 49 years, was admitted to St. Mary's Hospital in April, 1904, suffering from pyloric obstruction. A large mass was detected on abdominal palpation and laparotomy was performed on April 13th. The carcinomatous mass was found to involve a considerable amount of the lesser curvature of the stomach and to be slightly fixed to the posterior abdominal wall. The fixation appeared to have been produced by inflammatory adhesions. As the age of the patient and the state of the growth seemed to justify a radical operation it was decided to perform pylorectomy. This was accordingly done but in the separation of the malignant mass from its posterior relations a portion of the pancreas was torn and ligatured. The duodenum was joined to the cut edge of the stomach. The patient rallied well and went on favourably at first. On the 16th a certain amount of fluid was found to be escaping along a drainage track left in the abdominal wound. The fluid was alkaline. Methylene blue was given by the mouth to make certain that there was no gastric or duodenal leakage but no coloured fluid escaped, showing that the suture line was intact. The fluid from the fistula was carefully analysed by Dr. W. H. Willcox who found that it contained an amylolytic and a proteolytic ferment, both of which acted only in alkaline solution. Control experiments gave negative results. It was evident, therefore, that a pancreatic fistula had formed and it was decided that the effect of food on the secretion should be studied. Food, beef-tea, &c., were given by the mouth and some few seconds after they had been swallowed there was a definite secretion of pancreatic juice. The sight of food had a precisely similar effect, comparable in every way to that obtained when the salivary or gastric glands were similarly stimulated. The observations extended over some ten days, after which the patient became worse and died. Post mortem the pancreas was in a state of general suppuration but there was no fat necrosis. The evidence of this case supported Pawlow's original theory that pancreatic secretion was influenced by a nervous mechanism. The conditions under which the flow of pancreatic juice started were such that it could not be explained as the result of the formation and absorption of secretin. The work of Starling and Bayliss was conclusive as to the value of the intestinal contents—prosecretin and secretin—in maintaining a pancreatic flow but in this case there was support for the theory that stimulation of a sensory nerve could evoke a secretion here as in the case of the salivary glands.

OBSTETRICAL SOCIETY OF LONDON.

Vaginal Cystocele.—Exhibition of Specimens.—Presidential Address.

THE annual meeting of this society was held on Feb. 1st, Dr EDWARD MALINS, the President, being in the chair.

Dr. E. W. HEY GROVES read a paper entitled "A New Operation for the Cure of Vaginal Cystocele." After pointing out that the condition was one of hernia of the bladder through the interval between the levatores ani he proceeded to describe the anatomy of these muscles and to show how they formed the floor of the pelvis through the median gap in which the urethra and the vagina passed. Cystocele was accompanied by a divarication of the adjacent edges of the levatores ani. Dr. Groves suggested that the unsatisfactory results of all operations hitherto performed for this condition depended on the fact that they relied solely on the removal of the vaginal wall. He proposed, therefore, the following operation. A transverse incision [illegible] was made three centimetres behind [illegible] vagina was separated from the [illegible] the inner edges of the levatores ani were defined in each angle of the wound. The muscles were drawn together and stitched by two rows of suture. The vagina was united in the line of the original incision. The first case in which he had performed the operation occurred two years ago; the patient had since borne a full-term child and the cystocele showed no signs of recurrence. The patient's age was 35 years but he anticipated that the operation would be even more serviceable in old women because in them the levatores ani could be stitched together for a greater extent regardless of encroachment on the [illegible] in separating [illegible] the bladder.—[illegible] es upon which the operation was based appeared to be sound but he was inclined to think that at the age when relief was usually sought it would not be easy to find the separated borders of the levatores ani.

Dr. FRANK E. TAYLOR showed a Wandering Spleen which had simulated an ovarian tumour, had caused retroversion of the uterus, and had been removed by operation. It was completely contained within the pelvis and so had not given rise to any abdominal enlargement. The patient was a married nullipara, aged 29 years.—The PRESIDENT said that in the case of a patient whom he had seen some years ago with Sir Spencer Wells a diagnosis of ovarian cystic tumour was made but on operation it turned out to be a much enlarged spleen. He remembered a similar case of a spleen mistaken for ovarian tumour, where the spleen was much displaced and the pedicle axially rotated. He removed it with complete success.—Dr. HEYWOOD SMITH said that a similar case was sent to him as one of ovarian tumour. He made out that the tumour was a spleen displaced. Mr. J. Bland-Sutton removed it at his request. The patient recovered.

Mr. BLAND-SUTTON showed a specimen of Tuberculous Disease of the Body of the Uterus (probably primary). It had been removed by abdominal hysterectomy from a spinster, aged 46 years, who had suffered from menorrhagia for two years. A rounded body inseparable from the uterus could be felt in the hypogastrium. On opening the uterus a rounded sessile non-encapsuled tumour was found growing from the endometrium of the anterior wall. On section the tumour showed patches of caseation and on microscopic examination tubercle bacilli were seen. The most important clinical feature of the case was its similarity to a degenerating submucous fibroid.—Dr. P. HORROCKS said that he had seen several cases of tubercle of the lining membrane of the uterus but in all the cases the endometrium of the cervical canal and of the corporeal portion was affected. The clinical features more resembled cancer than fibroid.

The PRESIDENT delivered the Annual Address.

The following list of officers for 1905 was read:—President: Dr. W. R. Dakin. Vice-Presidents: Dr. A. H. Freeland Barbour (Edinburgh), Dr. Amand J. M. Routh, Sir William Japp Sinclair (Manchester), and Mr. Albert C. Butler-Smythe. Treasurer: Dr. George Ernest Herman. Chairman of the Board for the Examination of Midwives: Dr. John Phillips. Editor of the Transactions: Dr. Herbert R. Spencer. Honorary secretaries: Dr. Montagu Handfield-Jones and Dr. Robert Boxall. Honorary librarian. Dr. Arthur H. N. Lewers.

OPHTHALMOLOGICAL SOCIETY.

Malignant Disease of the Conjunctiva.—The Treatment of Corneal Ulcers by Quinine.—The Notation of Prisms.—Detachment of Retina.—Neuro-retinitis.—Exhibition of Cases and Specimens.

AN ordinary meeting of this society was held on Jan. 26th, Mr. JOHN TWEEDY, the President, being in the chair.

Dr. A. FREELAND FERGUS, in a paper read in his absence by Dr. F. R. HILL, related a case of Malignant Disease of the Conjunctiva. The patient was a girl, aged nine years, who was sent to him by Dr. Hill in November, 1903. On the lower part of the bulbar conjunctiva were some sprouting vegetations, with an appearance not unlike that seen in spring catarrh. The limbus and palpebral conjunctiva were unaffected. It had first been noted six months previously. The vision was $\frac{6}{9}$ and a portion was removed for examination. The pathological report was indefinite. Shortly after the rest was removed and the patient was sent back to Carlisle under Dr. Hill's care. The pathological reports of Professor R. Muir and Mr. C. Devereux Marshall showed the growth to be of an unusual character, probably a sarcoma, but its appearance left no doubt as to its being malignant. On March 21st, owing to its rapid extension, the whole contents of the orbit were removed and the patient was sent back on April 14th. On May 23rd she was again seen but the recurrence was so extensive that no operation was possible. The neighbouring glands were also involved and even at this time there were cerebral symptoms. The child died in October with the tumour of enormous size. The post-mortem examination showed extensive involvement of the brain. The growth was apparently a leuko-sarcoma.—Mr. J. H. PARSONS, who had examined the growth, said it appeared to him to be one of those rare cases of nævus or mole taking on malignant growth and he looked upon it as being probably an epithelial growth rather than a connective tissue one.

Mr. ARNOLD LAWSON read a paper on the Treatment of Corneal Ulcers by Quinine. He said that up to the present time the use of quinine in ophthalmology had been restricted to a very limited class of conjunctival and corneal affections but his observations, which had extended over four years, showed that it was a very powerful curative agent in a large variety of corneal ulcers not amenable to ordinary routine treatment, to which much more drastic measures were commonly applied. The sulphate of quinine dissolved carefully in just sufficient sulphuric acid to hold the salt in solution was recommended to be used in a 1 per cent. solution. The eyes should be soaked in the solution for five minutes four or five times a day and in addition a thorough irrigation daily by an undine filled with the solution was advised. It caused very little discomfort and patients used it readily but stronger solutions gave rise to pain and had no advantage. When the treatment was going to be successful improvement showed itself within a few days and if no manifest benefit was effected within a week it might be discontinued. The rapidity of healing under this treatment was at times remarkable and Mr. Lawson had seen many formidable looking ulcers heal by this treatment alone within a week. A list of several cases of corneal ulceration treated by this method within the last three years was appended to the paper.

Mr. CLAUD A. WORTH read a paper on the Notation of Prisms. He said that when they ordered a spherical or cylindrical lens they did not concern themselves with the refractive index of the glass of which it was made. They specified that it should have a certain definite effect upon a pencil of light and bring it to a focus at a certain specified distance. But prisms were numbered by most opticians according to the geometrical angle, so that if they wanted a prism which should deflect a pencil of light say four degrees they had to order a prism of eight degrees geometrical angle. The optician then supplied a prism the actual deflecting power of which was somewhere between three degrees and five degrees, according to the kind of glass of which it was made. It was much more convenient and accurate to number a prism according to the number of degrees which it deflected a pencil of light. Although this matter had been discussed before, yet he brought it forward in the hope that the society would make some definite pronouncement which would be accepted by spectacle makers in this country and inconvenience would thus be avoided.

Dr. D. J. WOOD (Cape Town), after referring to a case of Detachment of the Retina recorded by him in vol. xii. of the Transactions, described another case which he had recently seen which bore a strong likeness to the previous one. The patient was a Dutchman, aged 35 years, whose right eye had been lost five years before from perforating ulcer and the eye had been removed. Since that time the sight of the left had been failing but had rapidly deteriorated during the last five weeks. His vision was perception of light and he could just see large objects moving below. The pupil was active and the tension was normal. The ophthalmoscope showed two rounded detachments meeting and widening out above. The vitreous was clear. The vessels were more than double their natural size and were tortuous to a degree. Both arteries were constricted at frequent intervals, so that they looked like beads, while the veins had the appearance of strings of sausages. The constricting bands were retinal in origin and looked as if they were stitches holding the vessels down. In both cases it was difficult to follow the vessels, not only on account of the tortuosity, but also because the colour of the arteries and veins was so similar. There were no recent hæmorrhages but some patches that were seen probably represented old ones. The question was whether it was a proliferation of inflammatory material in the retina or a primary disease of the vessels. Probably serous exudation caused detachment of the retina but it was difficult to account for the lightness of colour of the veins which were seen in both cases.

Mr. LOUIS WERNER showed a sketch of a case of Neuro-retinitis of a severe type which occurred in one eye of an anæmic girl, aged 24 years. There was neither headache nor vomiting, the only symptom being a feeling of lassitude and for a time excessive thirst. There was no albumin present but the sugar reaction was doubtful. The left eye failed suddenly one morning and the vision was reduced to perception of movements of the hand. The field of vision was greatly contracted but the colour perception was good. The upper part of the disc was greatly swollen with large corkscrew-like vessels spreading out from it, while the lower part was white and atrophic but indistinct. In less than three days a perfect star of white lines appeared at the macula Under iron the swelling disappeared in three months and the vision improved to $\frac{6}{18}$ Dr Werner referred to a case reported by Sir W R Gowers in which retinal changes resembling those of albuminuric retinitis occurred in a chlorotic patient

The following case and specimens were exhibited —

Dr L COLE BAKER showed a Needle Holder for use with either straight or curved needles and a modification of Clark s Eye Speculum

Mr N BISHOP HARMAN showed a case in which there was Congenital Absence of the Internal and External Rectus Muscles

Mr H SECKER WALKER showed a radiograph of a case of Gunshot Wound in which two shots had entered the eye at the same hole and had lodged at the back of the orbit

---

BRITISH LARYNGOLOGICAL, RHINOLOGICAL, AND OTOLOGICAL ASSOCIATION —The general meeting of this society was held on Jan 13th in the rooms of the Medical Society, Mr W J Chichele Nourse, the President, being in the chair —Dr J Sim Wallace read a paper on Nasal Obstruction and Mouth Breathing —The President then delivered his address, of which the following is a *resumé* Having suitably acknowledged the honour conferred upon him the President referred to the former and the present work of the association He then alluded to the approaching celebration of the 100th anniversary of the birth of Senor Manuel Garcia, the inventor of the laryngoscope The rest of the address was devoted to the subject of Reason in Relation to Scientific Medicine The President pointed out the impossibility of arriving at truth except by the aid of the recognised rules of reason, for knowledge, he said, consisted of conclusions drawn by reason from the consideration of facts As, on the one hand records of facts alone did not constitute science, so, on the other the exercise of reason without regard to facts, as practised in the mediæval universities, was equally barren The principles of medicine were thus built upon accumulated records of facts by the methods of inductive reason, while the application of those principles to individual instances in the practice of the healing art was also dependent upon sound logic He then dwelt shortly upon the [illegible] composition and [illegible] I venture to think [illegible] place and on an [illegible] this association, stated in our constitution, is 'the advancement and diffusion of knowledge in all that relates to diseases of the throat nose, and ear' We are not merely students but professedly teachers of these subjects We teach, in the first place, by learning ourselves But, besides this, some of us are actually called upon to impart what we know to students in the course of hospital work It is our bounden duty therefore, to test and to re test the truth of our beliefs before imparting them to others Accurate and unbiased observation must be wedded to sound reason' —A vote of thanks was moved by Mr St George C Reid, seconded by Mr E Dennis Vinrace and carried unanimously —A number of clinical cases were then shown, each case being followed by a discussion dealing with its nature, treatment, and the like Among these cases were a case of Nasal Polypus with Deformity, shown by Dr W H Kelson, a case of Ulceration of the Palate for diagnosis, shown by Dr V H Wyatt Wingrave, and a case of Tertiary Syphilis of the Nose with Epiphora, shown by Dr D Mackenzie —The President showed a case of Fracture of the Larynx in a man aged 65 years He remarked that there was still some external deformity The accident occurred on Nov 23rd, or about seven weeks ago, so that there had been time for considerable repair to take place Dr Johnstone, who first saw the patient soon after the accident detected crepitus quite easily When the patient first came under his own notice crepitus could still be distinctly elicited Moreover an examination by the laryngoscope showed that the left cord was not only [illegible] istorted, it seemed as if the [illegible] outwards than it ought to be [illegible] the external deformity, the immobility of the cord, the crepitation and the great extravasation in the laryngeal tissues No doubt it was a case of simple and not of compound fracture Hence the absence of emphysema The mortality in recorded cases was very high Out of 69 cases of fracture of the larynx collected by Durham in his article in Holmes s 'System of Surgery' there were 53 deaths 30 cases were of fracture of the thyroid cartilage, of which 20 were fatal Almost all cases of which he had found records were compound fractures and it seemed as if this was one of the elements which produced the high mortality Some were the result of great violence and were attended by other injuries The œdema of the cords was an interesting point There was no doubt that the cords were very much swollen and infiltrated with fluid, particularly the left cord wh[illegible]

[illegible] in view of the infrequency of fracture of the larynx, thought it might be of interest to draw attention to a case which had been recorded by Dr G S Middleton of Glasgow[1] and which had for its clinical features two symptoms only—namely, hæmoptysis and subcutaneous emphysema The patient was a man aged 70 years, who, on rising from bed, slipped and in falling struck the right side of his head against the kitchen dresser He regarded the blow as entirely a trivial affair but shortly afterwards brought up about two teacupfuls of bright red blood In the course of a few minutes he was conscious of swelling of his neck and of some difficulty of breathing He was then taken to hospital and admitted to a medical ward Examination showed considerable subcutaneous emphysema of the face and the neck and this rapidly extended so as to involve the whole of the trunk There were urgent dyspnœa and cyanosis and it was impossible to obtain a view of the interior of the larynx but externally there was no evidence of injury Several surgeons who saw the case thought that the condition was due to fracture of one or more ribs with tearing of the lung substance, though no conclusive evidence in favour of this view could be obtained The patient died four days after admission At the necropsy there was discovered below the left vocal cord a cavity having a necrotic wall and leading to a necrosed thyroid cartilage It was by this avenue that air had reached the subcutaneous tissue The appearances were not those of syphilis, tubercle, or malignant disease and it was suggested that some small foreign body might have been responsible for the ulceration and necrosis, though no such body was discovered The patient had never made any complaint of symptoms suggestive of laryngeal disease and until the date of the hæmoptysis his friends had regarded him as a man in exceptionally good health Such a record might be said to have a special interest to members of that association, but, in addition, it aptly illustrated the necessity of keeping a wide outlook in whatever branch of practice a medical man might elect to engage It showed how a case which was essentially one of local disease in the larynx might present clinical features which brought it under the care of the general physician Specialism in some measure was, no doubt a necessity but to be conducted in harmony with the claims of sound practice it must maintain the wider outlook which had been defined in the President's thoughtful and earnest address However severely the practitioner might restrict the line of his practice he could not absolve himself from a responsibility which included the entire welfare of the patient

LIVERPOOL MEDICAL INSTITUTION —A meeting of this society was held on Feb 2nd Dr James Barr, the President, being in the chair —Mr F T Paul exhibited a patient suffering from Popliteal Aneurysmal Varix which had resulted from a bullet wound —Dr M Loewenthal demonstrated a specimen of Bothriocephalus Latus and mentioned the treatment he had adopted in the case from which it was obtained —Mr Paul read a note on Enterectomy for Cancer of the Colon Three recent cases were men[illegible] of the operation he had not lost a single case except when intestinal obstruction was present since he had brought the ends of the bowel outside at the time of the operation He would very much like to know what the real mortality was after primary end to end anastomosis of the large bowel

---

[1] Clinical Records from the Glasgow Royal Infirmary Alex Macdougall Glasgow 189

As a palliative operation he advised short-circuiting whenever it was possible rather than performing colotomy.—Mr. W. Thelwall Thomas had taken advantage of the method of operating described by Mr. Paul in several cases of colectomy and considered it a valuable advance. Cases being so often seen when marked obstruction had supervened he had found it impossible to unite the dilated proximal end of the divided gut to the atrophied and collapsed peripheral portion. —Mr. E. M. Stockdale, Mr. G. P. Newbolt, Dr. J. Hill Abram, Dr. G. C. Walker, Dr. W. Blair Bell, Dr. W. Carter, Dr. R. Humphreys, and the President also took part in the discussion.—Mr. T. C. Litler Jones related a case of Acute Hæmorrhagic Pancreatitis. The patient was a healthy woman, 26 years of age, subject to constipation. She was suddenly seized with severe abdominal pain and vomiting 46 hours before admission to hospital. Laparotomy was performed and there were found to be fat necrosis and about three pints of blood serum in the peritoneal cavity. This fluid was removed and the pancreas was incised in its long axis with a view to prevent further tissue necrosis due to the action of the ferment. The incision in the pancreas was packed with gauze which was removed 36 hours later. Except for some trouble with the abdominal incision owing to the digestive action of the pancreatic discharge the patient made an uninterrupted recovery.—Dr. W. B. Warrington read a paper on Compression Paraplegia with especial reference to Tumour of the Spinal Cord, and an account of a case of Endothelioma removed from the Cauda Equina. He pointed out that in any case of paraplegia the possibility of compression of the cord was to be considered. Tumours of the spinal cord were about ten times less frequent than cerebral tumours, but about half could be successfully removed, as against 4 per cent. of cases of cerebral tumour. The symptoms were progressive pain, motor paralysis, and sensory paralysis The clinical picture of a total block of conduction between the cord and the brain was described and reference was made to the splanchnic and somatic symptoms in these cases. Cases were then quoted to show that this "block" might be physiological and remediable, calling in selected cases for operative interference In the case of the patient with a tumour of the cauda equina there were symptoms of symmetrical affection of the sacral roots—pain, paralysis of the muscles moving the feet, loss of sensation in all the sacral and last lumbar area, disturbance of the bladder and rectum and loss of the bulbo- and ischio-cavernosi reflex. The tumour, which was removed by Mr. R. W. Murray, proved to be a malignant endothelioma and though marked relief occurred for some months the symptoms then reappeared and the case could only end fatally. The importance of differential diagnosis between lesions of the last part of the cord (conus medullaris) and the cauda equina was emphasised as in the latter case the surgeon often could operate satisfactorily. A brief account of the diagnostic features of the different lesions and their distinction from each other was given. In many cases of nervous disease the coöperation of physician and surgeon was most desirable.—The President Professor C. S. Sherrington, Mr. Damer Harrisson, Dr. Nathan Raw, Mr. Murray, and Dr. Hill Abram took part in the discussion.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Jan. 27th, Dr. A. Bronner being in the chair.—Dr. J. B. Hellier read a paper on Secondary Post-partum Hæmorrhage and described a recent case. The patient was a young married woman who was treated for partial placenta prævia at the seventh month by podalic version. For ten days she progressed without a bad symptom, there being no sign of sepsis and no lochial excess. On the tenth day she had a very severe flooding. This recurred on the seventeenth day after a further interval in which no bad symptoms were present. There was no further hæmorrhage and she made a good recovery. It is certain that no part of the secundines were retained in this case. Dr. Hellier discussed at length the causation and the treatment of this condition —Dr. A. G. Barrs, Dr. J. E. Eddison, Dr. H. Johnstone Campbell, and others took part in the subsequent discussion—Mr H. Collinson made some remarks on a case of Fibroid Polypus of the Bladder. The patient, a man, aged 33 years, was admitted to hospital, under the care of Mr. H. Littlewood, in a semi-conscious condition with dribbling of foul, blood-stained urine. He had suffered from occasional hæmaturia for 12 months and from great frequency of micturition and pain at the end of the penis for the last nine months. He died on the fifth day after admission from septic pyelonephritis. The [illegible] polypus of the bladder two inches in [illegible] on the upper and outer margin of the [illegible] This had obstructed the flow of urine from the right ureter, producing dilatation of it and the pelvis of the kidney. The tip of the polypus also obstructed the internal meatus of the urethra. Attention was drawn to the prominence, amongst the symptoms, of pain and frequency of micturition, and the physical characteristics of the tumour were cited as explanation.—Mr. Littlewood discussed the paper.—Dr. Campbell referred to the fact that in recent years the mortality from croupous pneumonia had not only shown no signs of diminution but had on the other hand considerably increased, in spite of the advance that had been made in the treatment and in the case-mortality of most other diseases. He insisted upon the necessity, in the matter of treatment, of recognising that pneumonia is a general disease with a local manifestation and said that he considered that the main indications were to take off pressure upon the heart and to lessen the work that it had to perform rather than by stimulating it to try to increase its motive power, to keep the kidneys well flushed by the administration of plenty of water, and to avoid overloading the stomach with food. He deprecated the routine use of drugs like digitalis and strychnine and recommended the use of potassium iodide as a vaso-dilator and in suitable cases creasote to prevent fermentation in, and consequent distension of, the stomach. He further dwelt upon the necessity of avoiding any disturbance of the patient that could possibly be avoided and especially thought that examination of the lung should be made to the smallest possible extent when once the diagnosis had been established. —Dr. Barrs and Dr. Eddison discussed the paper and Dr. Campbell replied.—Various cases and pathological specimens were shown by Mr. A. L. Whitehead, Dr. Barrs, Dr. T. Churton, Mr. E. Ward, Mr. W. H. Brown, Dr. C. M. Chadwick, Dr. Hellier, Dr. E. F. Trevelyan, Mr. Littlewood, Dr. Carlton Oldfield, Mr. G. Constable Hayes, Dr. T. Wardrop Griffith, and Mr. R. Lawford Knaggs.

MIDLAND MEDICAL SOCIETY.—A meeting of this society was held at Birmingham on Feb. 1st, Dr. E. W. Wood White, the President, being in the chair.—Dr. J. G. Emanuel showed a case of Spina Bifida Occulta in a child, aged two years. In the dorsi-lumbar region of the spine there was a diffuse overgrowth of long [illegible] ed by this hair seemed in no way [illegible] the spine at the juncture of the co [illegible] was evidence of incomplete closure of the primitive medullary groove in the form of a well marked dimple in the middle line. The child, otherwise perfectly well developed, suffered from incontinence of urine but this was held not to point to any defect in the cord, as there were no other signs such as talipes, altered knee-jerks, &c.—Mr. George Heaton showed a Sarcoma of the Epididymis removed from a man, aged 28 years, who had noticed a tumour at the back of the right testicle for eight weeks It increased rapidly in size at first but latterly had not enlarged much. The testis could be felt in front of the lower part of the swelling. The tumour on removal was of about the size of a large orange. The testis, normal in size and appearance, was situated at the front part and not involved in the growth. There was no enlargement of the vas deferens or other constituents of the cord. Microscopically the tumour was a mixed round-celled and spindle-celled sarcoma.—Dr. A. Stanley Barnes showed specimens from a case of Cerebral Tumour in which there was secondary growth in the spinal pia mater. The patient was a boy, 11 years of age, who [illegible] suffered from morning vomiting, slig [illegible] of sight. After an illness [illegible] symptoms abated and his [illegible] was able to read large print. The symptoms recurred [illegible] months before admission to the Queen's Hospital, the patient having been practically well during the interval. In hospital he grew gradually worse, his main symptoms being headache, vomiting, loss of sight (due to post-neuritic atrophy), wasting, and convulsions. All the reflexes were lost several weeks before death. Post mortem there was found a large sarcoma of the frontal lobe, apparently growing from the ependyma of the anterior cornu of the lateral ventricle. The floor of the fourth ventricle and parts of the other ventricles showed secondary growths and at the base of the brain and

around the spinal cord the pia mater (and to a
the arachnoid) were enormously thickened to form
continuous mass of sarcomatous growth, constituting a
for the spinal cord The posterior root ganglia and some of the roots of the cauda equina were greatly enlarged by growth The secondary affection of the ventricular walls and pia mater probably occurred as a result of rupture of the tumour —Dr J Douglas Stanley read a paper on Syphilitic Disease of Some Viscera

CLINICAL SOCIETY OF MANCHESTER —A meeting of this society was held on Jan 10th Dr E S Reynolds the President being in the chair —Mr E Stanmore Bishop read a paper on the Surgical Aspect of Biliary Calculi, illustrated by means of patients and specimens The progress of abdominal surgery he said, had been great since asepsis had permitted surgeons to substitute ante mortem for post mortem examinations of the viscera therein contained and both diagnosis and treatment of biliary calculi had shared in the general advance The diagnosis of these conditions had become much clearer since greater emphasis had been laid upon the fact that gall stones as such had no existence for the surgeon It was only when associated with inflammatory conditions in the channels containing them that they became appreciable both by the patient and the surgeon Just in the same way the stercoliths in an appendix had no pathological significance until associated with some inflammatory change in the appendix itself Such a combination necessitated the existence of certain symptoms which were pathognomonic rise of temperature in a certain manner—the steeple chart of Moynihan and the cholangic angle of Murphy, pain of a definite kind and radiation in a definite way followed by tenderness of the affected region appreciable by Murphy's test and certain reflexes Murphy's test was described In regard to treatment, the advances in technique were illustrated by the different operations practised in 22 cases and their results The necessity of at least temporary drainage in all cases was shown to be a consequence of the conditions present Operation *à deux temps* as formerly practised by himself in common with other operators was shown to be wrong in principle and the difficulties necessarily dependent upon such a method were illustrated by cases Preliminary dosing with calcium chloride after the method of Robson was strongly supported by his experience The patient separation and ligature of all adhesions before any attempt at removal of calculi were emphasised Various methods of drainage were discussed The two main incisions of Robson and Rutherford Morison were described and illustrated by cases in which they had been used Amongst the patients shown was one in whom operation had been carried out at the fifth month of pregnancy without disturbance and the child born at full term was also shown Mr Stanmore Bishop expressed his obligation to Dr R A Paton of Harpurhey and to Mr Harold J Moon of Levenshulme by whose courtesy these patients were shown

ROCHDALE AND DISTRICT MEDICAL SOCIETY —A meeting of this society was held on Feb 2nd Mr W Pooley the President being in the chair —Mr R Burdett Sellers opened a discussion on Ambulance Work and its Relation to General Practitioners After a historical survey of the origin and subsequent development of the ambulance movement Mr Sellers described the objects kept in view by the St John Ambulance Association emphasising the fact that in case of accident the aim was not to supplant the medical man but to prevent death and to minimise suffering pending his arrival Mr Sellers described several typical cases in which he claimed that lives had been saved by ambulance men He also cited the testimony of army surgeons and distinguished medical civilians in favour of ambulance work during the recent Boer war and elsewhere —Dr A Wallace believed that ambulance work did some good but thought that the instructors should be paid by the State —Mr S T Lord insisted on the amount of good done by ambulance men and also on the opportunity given to the lecturers to expose quackery —Mr W Stanwell admitted the value of ambulance work but pointed out that
there were cases of ambulance
down by Mr Sellers —Dr J A
the opposition to ambulance w
disapproved of the movement while admitting that it did a certain amount of good His disapproval was due to the conduct of ambulance men, one of whom, e g , after treating an obvious fracture for some time as a sprain, disputed
was obvious
n with
more or less
e army
medical staff
to do
He disapproved of the ambulance movement and thought that many cases which received first aid would be better if left alone until the medical man arrived —Mr Sellers, in reply repeated his main contention that the chief advantage of ambulance work was that it lessened loss of life and suffering

BRIGHTON AND SUSSEX MEDICO-CHIRURGICAL SOCIETY —A meeting of this society was held on Feb 2nd, Mr G Morgan the President being in the chair —Mr R F Jowers showed a Renal and a Ureteral Calculus which he had removed together with a large hydronephrotic kidney, from a woman who made a good recovery The renal calculus weighed seven drachms, the ureteral one which weighed half an ounce was situated at the lower end of the ureter and had been felt per vaginam before the operation He also exhibited a Fractured Patella which he had wired two and a half years before the patient's death and which showed perfect bony union —Dr Walter Broadbent showed a case of Leucocythæmia in which there were a very large spleen and also numerous enlarged glands The blood contained one white corpuscle for every three red, 40 per cent of the leucocytes were myelocytes Hypodermic injections of arsenate of iron having been given for six weeks without any good effect a trial was now being made of the x ray treatment He also exhibited a Fusiform Aneurysm of the Second Part of the Arch of the Aorta which had ruptured into the trachea —Dr F Hobhouse brought forward a case of Sporadic Cretinism The patient was a child aged six years who weighed 1 stone 10 pounds had not learned to walk and was deficient in intellect He also showed a case of Cerebral Diplegia in which the legs exhibited spastic movements with exaggerated reflexes but the arms were hardly affected The sphincters were paralysed and there was internal strabismus of the right eye The head was small and an abnormal depression could be felt on the vertex Intelligence seemed fair the squint had existed when the child was six months old but the parents had not noticed the spasticity of the legs till three months later —Mr W Turner showed a Fibroid Tumour of the Ovary weighing seven pounds removed by operation —Mr T. H Ionides exhibited a Two and a Half Months Fœtus found in the abdominal cavity during an operation for ruptured extrauterine fœtation

GLASGOW MEDICO CHIRURGICAL SOCIETY —A meeting of this society was held on Jan 27th Dr D N Knox being in the chair —Dr J H Nicoll by means of a lantern demonstrated the steps of an operation for the Radical Cure of Inguinal Hernia —Dr Nicoll also showed specimens from a series of cases of Hernia of the Ovary —Dr A Freeland
Fergus read a paper on Some
logical Investigations of the
Pollock gave a lantern demo
Organisms found in the Conjunctival Sac —Dr J Walker

(2) a Hard Piece of Bone which was impacted in the subglottic region of the larynx in a child aged eight months These bodies were removed by opening the trachea and passing a narrow strip of gauze through the larynx into the pharynx The end in the pharynx was caught by forceps and the gauze gently pulled upwards and the foreign body was dislodged and entangled in the meshes of the loose gauze

BRITISH ELECTRO THERAPEUTIC SOCIETY —The annual meeting of this society was held on Jan 27th when the following were elected as officers for the ensuing year —President Dr Donald Baynes Vice Presidents Dr Dawson T D Turner and Mr Chisholm Williams Council Dr J Allan, Dr D Arthur Dr G L Batten, Dr James Berry, Dr T A Codd, Mr R H Cooper, Mr Hall Edwards Dr G H Graham Dr W S Haughton, Dr G Herschell Dr T Donald Pollock Mr A D Reid, Dr S Sloan, Dr Septimus P. Sunderland and Mr C A J Wright Treasurer Dr H
Assistant treasurer

Dr. H. Lewis Jones. Honorary secretaries: Dr. H. E. Gamlen (West Hartlepool) and Dr. E. R. Morton (London).—The annual address by Dr. J. Macintyre of Glasgow was read by the retiring President, Dr. H. Lewis Jones, Dr. Macintyre being unavoidably absent through illness.—At the annual conversazione which followed there was a full attendance of members. Among the novelties shown an ingenious arrangement of an induction coil and electrolytic break for heating cauteries from the continuous main current was especially noted. It was shown by Mr. A. C. Cossor. The temperature of the burner was under perfect control and its consumption of current was very small.—Messrs. Watson and Sons showed a Glove for use by x ray workers as a protection against dermatitis and also a new form of X Ray Tube.—Mr. Leslie Miller showed the Apparatus for Winding his Jointless Section Coils and also instruments for Measuring the Current through an X Ray Tube.—Various interesting and novel instruments and apparatus were shown by other exhibitors and, taken as a whole, the exhibition gave evidence of distinct advancement during the past year.

KIDDERMINSTER MEDICAL SOCIETY.—A meeting of this society was held on Feb. 3rd, Mr. J. L. Stretton being in the chair.—Mr. Stretton showed: 1. A man, aged 42 years, whose Wrist he had Excised for Tuberculous Disease. The whole of the carpus, the ends of the metacarpal bones, and the ends of the radius and the ulna were removed through a single dorsal incision. The result was satisfactory; within two months of the operation he was able to use a spade. 2. A man, aged 75 years, who Fractured his Patella Transversely. It was brought together with wire after the method of Mr. Barker and he was able to walk about in ten days. 3. A woman, aged 35 years, treated successfully with Professor Sclavo's serum for Anthrax.[1] 4. A Dermoid Cyst of the Right Ovary removed from an unmarried woman, aged 53 years. It contained a mass of hair and fixed to the upper end of the cyst wall was a portion of bone resembling an upper jaw with a row of six teeth.—Dr. Bertram Addenbrooke showed: 1. Temperature Charts of Three Cases of Pneumonia under his care in one week, all following influenza. One subsided by lysis and two by crisis. 2. An Aural Polypus. 3. A large Cancerous Tumour removed from the Abdominal Wall. 4. A large Mushroom-shaped, Phosphatic Vesical Calculus which had formed in a vesico-vaginal fistula which resulted from the operation for vaginal hysterectomy.—Mr. A. C. Oldham read a paper on Peripheral Neuritis. He described at considerable length a case which he had had under his care complicating pregnancy; the child was born at full time and was healthy and the mother made a good recovery.—Some new ethical rules having been adopted the meeting terminated.

ROYAL MEDICAL SOCIETY, EDINBURGH.—At a meeting of this society held on Feb. 3rd Dr. W. E. Carnegie Dickson demonstrated some specimens of Pathological Marrow conditions. He prefaced his remarks by an account of the anatomy and the histology of the marrow and then proceeded to show specimens of various degenerations. He next discussed more fully the development, the physiology, and the pathology of the various marrow cells and concluded by describing the changes in the marrow which accompanied various pathological conditions of the blood.—Dr. H. J. Dunbar read a paper on the Value of Examination of the Blood in Diagnosis. He commenced by discussing the histological examination of the blood in various conditions and then went on to describe the value of other methods of examination, such as the determination of the freezing point or of the alkalinity of the blood and the various bacteriological reactions.—Dr. L. S. Milne read notes of a case of Adherent Pericardium.

---

[1] THE LANCET, Feb. 4th, 1905, p. 292.

NATIONAL DENTAL HOSPITAL.—The annual general meeting was held at the hospital in Great Portland-street, W., on Jan. 31st, Mr. Alfred Farquhar, the treasurer, being in the chair. Among those present were Mr. W. Ward Cook, Mr. W. H. Grabham, Mr. F. Canton, Mr. Herbert J. Relph, Dr. James Maughan, Mr. S. F. Rose, and Mr. Sidney Spokes, Dean. The report for 1904 unfortunately shows a deficit amounting to £774 and the committee of management earnestly appeals for aid to decrease this debt. The quality and the quantity of the work done have been well maintained.

Reviews and Notices of Books.

Human Embryology and Morphology. By ARTHUR KEITH, M.D. Aberd., F.R.C.S. Eng., Lecturer on Anatomy, London Hospital Medical College; Examiner in Anatomy, University of Aberdeen, and in the Natural Science Tripos, University of Cambridge. Second edition, revised and enlarged. Illustrated with 316 figures in the text, of which 64 are new in this edition. London: Edward Arnold. 1904. Pp. 402. Price 12*s.* 6*d.* net.

THIS the second edition of Dr. Arthur Keith's most useful volume has undergone careful revision and, without being materially enlarged, has kept pace with the work of other embryologists, has been rendered more precise, is more fully illustrated, and has been in every way improved. The author states in his preface that in this edition the chapters dealing with the early development of the human embryo and the formation of the placenta have been entirely rewritten; that much of the chapter dealing with the uro-genital system has been amended; that many additions have been made to the chapters on the central nervous system; and that additions have been made to the remaining chapters on the bones and epiphyses, heart, blood. lungs, diaphragm, peritoneum, cæcum, and appendix.

We consider the production of a good work on embryology to be one of the most difficult tasks that the physiologist can undertake. Its satisfactory execution demands great powers of accurate observation and unwearied patience, for the object of his research is undergoing constant change, while the parts are extremely delicate, require for the most part great familiarity with the microscope, and easily break down or become displaced when sections are required, however sharp the knife may be and however steady the hand. Then the several regions of the rudimentary organism not only alter in form and position but they are in process of development and that which is at one time little more than a minute and an amorphous mass of cells rapidly assumes the form and the proportions as well as the structure of a complex organ. But even if he be a good observer the embryologist must not only comprehend what he sees but he must be a good draughtsman possessed of much literary skill and power of expression so that he may build up for the learner in stereographic fashion, if the term may be allowed, the concomitant structural and morphological changes which have been observed in a succession of sections in such a manner that a concrete conception of the growing and developing organism at different periods of its life may be obtained.

Dr. Keith pursues a different track from the majority of writers on embryology, for instead of commencing with a description of the ovum he begins with an account of the outgrowths which form the face at about the middle of the first month of fœtal life, pointing out the teratological results of their imperfect development or non-union as seen in harelip and cleft palate. The modes of formation of the nasal duct, of the naso- or anterio-palatine canals, of the Vidian, pterygo-palatine and infra-orbital canals, with the relations of the rudimentary organ of Jacobson, are all fully and instructively given. The development and the ossification of the mandibular arch, with the relations of the palate and pterygoid processes and quadrate bones, as well as the derivation of the malleus and the auditory ossicles, are shown with a clearness that would have gladdened the heart of Kitchin, Parker, and Huxley.

The author has had the advantage of the coöperation of Dr. G. Elliot Smith in the section on the development of the brain and the spinal cord. The cause of the oblique course of the roots of the spinal nerves is shown to be the rapid growth of the spinal column and the degree to which the obliquity extends in different parts of the vertebral column is given on the authority of Professor R. W. Reid. It varies from two vertebræ in the lower cervical region to five in the lumbar and ten in the coccygeal region. The differentiation of the spinal part of the neural tube is described, showing that of the cells which at the sixth week form the medullary plates some become neuroglial—or elongated and branched supporting—cells; others situated in the outer zone of the tube wall form a meshwork; others more centrally placed form the ependyma, and some situated in the middle zone have their interspaces filled with neuroblasts. The neuroblasts are produced from germinal cells lying in, or near, the inner zone. Those in the roof and floor of the neural tube scarcely undergo any proliferation but two lateral centres of proliferation appear, one of which, the dorsal lamina, contains cells that are connected subsequently with the ingrowing fibres of the dorsal root, and a ventral lamina, at which the cells of the anterior horn are produced and from which the fibres of the anterior root arise. The development and the date of *myelinisation of the columns of Goll, Burdach, Flechsig*, Clarke, and Gowers are given with those of the intermediate and pyramidal tracts. The middle zone, above mentioned as filled with neuroblasts, forms the horns and the grey matter of the cord. The cerebellum is described as developed in lateral plates or folds proceeding from the dorsal laminæ of the anterior part of the hind brain; these fuse in the middle line, the line of fusion becoming the vermis. Towards the end of the third month the cerebellar plate becomes demarcated into anterior, middle, and posterior lobes which are separated by two transverse fissures and are recognisable in nearly all mammalian cerebella. The parts in the fully developed adult cerebellum proceeding from each of these lobules is given with the mode of formation of the three cerebellar peduncles which are shown to be highly complex. Dr. Keith points out that the cerebellum reaches its greatest development in primates amongst mammals and in swimming vertebrates, in both of which groups the equilibrium of the body is finely adjusted.

A much fuller account of the development of the respiratory organs is to be found in Dr. Keith's treatise than elsewhere, for he shows the mode in which the branchial system and the swim bladder of fishes and amphibians undergo evolution into the mammalian respiratory system. This is effected by the formation of a respiratory passage leading from the pharynx to the incipient lungs, by modifications of the last pair of branchial arches, and by changes taking place in the branchial muscles of the lower animals leading to the formation of a muscle of inspiration or diaphragm and in the muscles of the body wall ending in the formation of the muscles of expiration.

The development of the uro-genital system is given in considerable detail, the description of the successive changes being founded on the researches of Keibel, Berry Hart, J. P. Hill, and F. Wood Jones. It is shown that in the first instance an organ termed the pronephros appears in the intermediate cell mass or solid protrusion into the cœlom on either side of the incipient mesentery and in the cervical region. It consists of tubules which open externally into the cœlom or peritoneal cavity by trumpet-shaped ciliated ends representing the segmental or nephridial tubules of the Vermes. Internally they are connected with the anterior part of the Wolffian duct and soon disappear. In the second month of intra-uterine life the mesonephros or Wolffian body is fully developed. This consists of numerous tubules which have a blind extremity containing a glomerulus and open internally into the middle part of the Wolffian duct. These tubules secrete urine which the Wolffian duct conveys to the cloaca of the hind gut just as in the frog. Finally, the tubules opening into the lower or posterior part of the Wolffian duct persist, becoming part of the genital system *in the male but functionless in* the female. In the male the Wolffian duct forms (1) the tube of the epididymis which is coiled up in the globus major, the body, and the globus minor of the epididymis, (2) the vas deferens and common ejaculatory duct, and (3) the vesiculæ seminales. The stalked hydatid frequently seen on the upper extremity of the testicle is the upper or anterior extremity of the Wolffian duct. The genital tubules of the Wolffian body become the rete testis, vasa efferentia, and coni vasculosi. The renal tubules of the Wolffian body form (1) the vasa aberrantia found in the globus minor and (2) the paradidymis or organ of Giraldès sometimes discoverable in the cord above the globus major. The permanent kidney is derived from two elements: (1) a diverticulum of the Wolffian duct which gives origin to the ureter, pelvis of the kidney, calyces, and collecting tubes, and (2) the posterior segment of the intermediate cell mass, whence arise the glomeruli, vessels, and connective tissue. In the female a second tube forms in the intermediate mass named the Mullerian duct, the upper part *of which becomes the Fallopian tube. When the ovary* and the tube migrate to the pelvis the Wolffian mesentery which comes to form the meso-salpinx is also drawn within the pelvis and with it all the Wolffian remnants; a hydatid attached to the meso-salpinx (part of the broad ligament) represents probably the pronephros and may become cystic; the Wolffian duct runs in the meso-salpinx to the uterus and terminates in the vulval cleft behind and to the outer side of the urethra. The upper part of the duct only remains in women; the lower parts disappear or if they persist constitute the duct of Gaertner. The genital tubules of the Wolffian duct, those, namely, which are connected with the ovary, persist and form the epoophoron or parovarium or organ of Rosenmuller and frequently form large cysts. The renal Wolffian tubules persist, lie between the ovary and the uterus, and form the paroophoron. This account, which we have condensed, gives the results of recent researches and is a good piece of work, constituting a considerable advance on the statements usually made in text books.

The formation of the placenta is very interestingly given. It is shown that the chorion arises from a combination of two elements, the trophoblast or enveloping layer of epiblast and an extension from the somatic mesoblast. The trophoblast is divisible into a basal layer and a mass of cells to which the term "syncytium" is applied. The cells possess remarkable phagocytic power and burrow into the thickened and vascular mucous membrane of the uterus in a systematic and regulated manner; they absorb the tissue with which they come into contact and lay open the blood vessels of the uterine mucous membrane. The maternal blood escapes into spaces inclosed by the syncytial processes or into lacunæ formed by the vacuolation of the processes. In certain circumstances, he adds, at present unknown, syncytial cells escape into the general *circulation and form malignant* growths. Drawings are given showing the relation of the syncytium and the blood spaces of the placenta.

We have no further space to give to Dr. Keith's treatise except to add that it should be in the hands of every physiologist and gynæcologist in the kingdom.

Syphilis de l'Œil et de ses Annexes. (Syphilis of the Eye and its Adnexa.) Par le Dr. F. TERRIEN, Ancien Chef de Clinique Ophtalmologique de la Faculté de Paris. Paris: G. Steinheil. 1905. Small 8vo, pp. 316. Price 4 francs.

THE manifestations of syphilis in the eye and the parts adjoining constitute a large and important chapter in the history of that disease. The eye seems to absorb more than its due proportion of syphilis as compared with other regions of the body but it is to be borne in mind that in this limited area are crowded together nearly all the tissues found elsewhere, as skin and connective tissue, blood vessels, nerves, muscles, bone, and gland, besides some special structures like the cornea, the lens, and the vitreous humour which, however, rarely present any appearances that are directly attributable to the action of the syphilitic virus. It is fortunate, however, that when the eye is attacked owing to its exposed position the onset of the disease is recognisable at an early period and appropriate remedies, if skilled assistance is at hand, can be applied.

In Dr. Terrien's treatise there is an introductory chapter entitled "Notions Anatomiques" which gives a short account of the nomenclature and disposition of the parts entering into the formation of the eye and the parts adjoining. There are also a few paragraphs describing the use of the ophthalmoscope. The volume is divided into three parts, the first discussing hereditary syphilis; the second dealing with symptoms of acquired syphilis, as seen in primary, secondary, and tertiary syphilis; and the third giving the treatment of the various forms and stages. The author thinks that the distinction between early or infantile hereditary syphilis and delayed hereditary syphilis or the syphilis of youth should be preserved. He intimates that considerable caution should be exercised in speaking of syphilis transmitted to a third generation through a mother who is only the subject of hereditary syphilis, since there is always the possibility of the father being infected. He cites the observations of Mr. E. Treacher Collins, M. Huguenin, and others, but is of opinion that, however likely it may be, the fact has not been scientifically established. The various forms of infantile hereditary syphilis are well given and include iritis with its several forms of serous and acute iritis, iritis combined with keratitis, and gummatous iritis; retino-choroiditis, which presents itself under the various types of smaller or larger pigment spots in the retina, affecting both sides; peripherally situated accumulations of pigment with little impairment of vision; yellowish-white masses which, if they fuse together and advance towards the centre, may seriously embarrass vision; and, lastly, that type in which the pigment either disappears or becomes greatly hypertrophied and vision is much impaired, though blindness is not produced. Then follows a description of optic neuritis, of changes in the retinal vessels, of various congenital malformations, such as coloboma, buphthalmia, microphthalmia, and of that form of nystagmus to which he has applied the term "nystagmus of intra-ocular origin." The manifestations of syphilis in youth are next considered and a particularly good account of interstitial keratitis is given. The author observes that whilst Hutchinson thought that this affection was almost always a sign of inherited syphilis later authors have assigned a smaller proportion of cases to heredity as a cause, Saemisch considering that 62 per cent. of cases of interstitial keratitis were due to inherited syphilis, Alexander 36 per cent., and Michel 55 per cent.

A long section is devoted to affections of the eye due to acquired syphilis. The most frequent seat of chancre is stated to be the inner angle owing to the stagnation of the tears in this region. The diagnosis between primary chancre and hordeolum, tuberculous ulceration, lupus, epithelioma, and malignant pustule is given in full. Dr. Terrien does not mention the atrophy, the bleaching, and the falling out of the cilia and of the hairs of the eyebrows which often accompany or follow a chancre of the lid. The secondary lesions occurring in the choroid, optic papilla, and nerve are illustrated by good woodcuts. Under the secondary lesions he includes exophthalmia and various affections of the accessory organs, such as roseola and exanthema of the lids, papular and mucous affections of the conjunctiva, affections of the lacrymal apparatus, and such affections of the orbit as osteoperiostitis, gummata of the orbit, and exostosis and osteomata. The conditions which he attributes to tertiary syphilis are gummata, motor paralysis and contractures, and neuralgia especially of the fifth nerve. The sequelæ of syphilis, tabes and general paralysis, with the numerous and remarkable modifications of the reflex actions of the iris which are usually associated with lesions of the central nervous system, are very interestingly described. We have only space to add that in regard to the treatment of syphilis Dr. Terrien considers that iodine and mercury are the sheet anchors on which reliance must be placed. Taken internally or applied by friction neither is to be depended on, but daily injections made in the gluteal region prove of the greatest service and the best solution for use as an injection is the following: mercury biniodide, 20 centigrammes (about three grains); pure sodium iodide, 20 centigrammes; and distilled water, 10 cubic centimetres. Dr. Terrien's book is very sensibly written and is evidently the outcome of much experience.

Orthodontia and Orthopædia of the Face. By VICTOR HUGO JACKSON. London and Philadelphia: J. B. Lippincott and Co. 1904. Pp. 517. Price 21*s.* net.

DURING the last few years many books have been published on the irregularities of the teeth but only a few of these volumes have treated the subject in anything like a satisfactory manner. Treatment to be rational must be based upon a correct understanding of the underlying causes but this fact seems to have been totally disregarded by many of the authors who apparently are imbued with but one main idea—namely, to bring irregular teeth into a correct line whether there is or is not room in the arch. Too often works have been published with the idea of advocating this or that system of treatment, the difference in the systems lying not in the application of different underlying principles but in the slightly varying methods of applying force to teeth. The present volume is not an exception. Etiology is but scantily dealt with, even the views enunciated are open to question, and the main part of the book is devoted to a description of the author's so-called system of regulating. We quote the author's words: "*Jackson System of Anchorage.*—Attention is called to the method devised by me for anchoring appliances to the teeth with spring-clasp attachments. These are fitted to one or more of the molars or bicuspids on each side of the arch, in some cases depending entirely on them for anchorage; in other cases using in conjunction with them partial clasps on adjoining teeth. The appliance is made in such a manner that it can be removed or replaced when desired for cleansing on putting on more pressure.' Beyond the anchorage the methods recommended differ but little from those used by many others. A detailed description is given of plates for mechanically correcting the various irregularities met with in practice. As an appendix there are 44 plates containing illustrations of regulating apparatus.

LIBRARY TABLE.

Manual of Serum Diagnosis. By Dr. O. ROSTOSKI, University of Wurzburg. Authorised translation by Dr. CHARLES BOLDUAN. London: Chapman and Hall, Limited; New York: John Wiley and Sons. 1904. Pp. vi.-86. Price $1 net.—This little book gives a very clear account of the present state of our knowledge on the subject of agglutination and precipitation and their application to diagnosis. The first chapter deals with the principles upon which the technical procedures used in the different tests are founded. In the second chapter the Gruber-Widal test for the presence of enteric fever is considered; the author recommends the use of a pipette, such as that belonging to the Thoma-Zeiss hæmocytometer, for the purpose of making the requisite dilution of the serum and considers that to be called positive the reaction should take place in a dilution of 1 in 60. As a rule, the agglutinating power passes off quickly after the cessation of the disease. The existence of a strong reaction in a case which clinically is not enteric fever may point to some unusual localisation of typhoid bacilli, as in a case of nephritis and in one of pneumonia here alluded to, both of which turned out to be due to infection with this organism. Dead bacilli may be used for the agglutinative reaction and we may thus avoid the danger of using virulent cultures. "Ficker's diagnostic," a preparation of this nature, has given very satisfactory results; it is to be regretted that so far the exact manner of its preparation has been kept secret. In cases which are clinically enteric fever but fail to give a Widal reaction the serum of the patient should be tested for its agglutinating action on paratyphoid bacilli. In diseases other than enterica (Chapters 3 and 4) agglutination is not, according to this author, of any diagnostic value; he does not, however, make any allusion to Malta fever in which practical use has been made of this phenomenon. On the other hand, agglutination is valuable in many cases to the laboratory worker as a proof of the nature of a particular organism. The precipitation test for human blood (Chapter 5) seems now to have taken its place as a valuable procedure in medico-legal investigations. The book before us has no index, though a table of contents at the beginning serves to supply most of the references required. An appendix records some interesting observations by Dr. R. J. Wilson on the distribution of bacilli, normal and agglutinated, in fluid media For a volume of 66 pages, of some 220 words each, the price seems somewhat high.

A Manual of Toxicology. By ALBERT H. BRUNDAGE, A.M., M.D., Phar.D., Professor of Toxicology and Physiology in the Rhode Island College of Pharmacy and Allied Sciences. *Fourth edition, revised and profusely* illustrated. London: Baillière, Tindall, and Cox; New York: The Henry Harrison Co. 1904. Pp. 401. Price 8*s.* 6*d.* net.—That three editions of this manual have been absorbed in as many years and that this fourth edition is now called for is the best evidence of its popularity amongst students of toxicology. In his various capacities as student, pharmacist, physician, and teacher the author has been impressed with the importance of illustration and the immeasurable advantages to be derived from it. He has therefore endeavoured to provide that this edition should present ample pertinent illustrations. Dr. Brundage hopes that through this association of fact and illustration many of the toxicological facts may be simplified and better disseminated. The ten coloured plates showing the conditions of the stomach in cases of poisoning are beautifully executed and faithfully portray the states of that organ. The whole book is clearly written and so well arranged and indexed that rapid reference may be made to it. Part VIII., which deals with coma, its interpretation and treatment, is valuable, as is also Part X., which treats of chronic poisoning and drug habits. The Dose Table and the Table of Maximum Daily Doses should both prove of great utility.

Reports and Analytical Records

FROM

THE LANCET LABORATORY.

ALPHOZONE.

(FREDERICK STEARNS AND CO., DETROIT, MICHIGAN. AGENTS: THOMAS CHRISTY AND CO., 4, 10, AND 12, OLD SWAN-LANE, UPPER THAMES STREET, LONDON, E.C.)

"Alphozone" is an organic peroxide and occurs in the form of a white crystalline powder soluble in water. It is decidedly more stable than the metallic peroxides or peroxide of hydrogen itself. On adding solution of permanganate of potassium to "alphozone" no change takes place until the fluid is warmed when mutual decomposition sets in and oxygen gas is evolved. "Alphozone" does not *respond to the chromic acid test for peroxide of hydrogen* until it is neutralised (for it is strongly acid to test paper) with ammonia. There is then slight effervescence and on adding sulphuric acid and chromate of potassium and shaking up with ether the characteristic blue colour of perchromic acid is obtained. "Alphozone" consists in reality of a *substitution product of hydrogen peroxide in which the* hydrogen atoms are replaced by two succinyl radicles, its formula being $(C_4H_5O_3)_2O_2$. It is stated to be non-poisonous whilst exhibiting powerful germicidal properties. According to bacteriological tests "alphozone" shows a germicidal power or efficiency equal to that of corrosive sublimate.

PINE TAR SOAP.

(THE PACKER MANUFACTURING CO., NEW YORK. AGENTS: MAY, ROBERTS, AND CO., 9 AND 11, CLERKENWELL ROAD, LONDON, E.C.)

This is a very agreeable soap to use and, moreover, according to our tests, it contains no free alkali. The soap has a pleasant odour of pine oil and whilst giving a satisfactory lather *is economical in use. It is free from* ingredients of an irritating nature and is therefore harmless to delicate skins

KALITZER SPARKLING WATER.

(NATHANIEL SMITH AND CO., 373, HIGH STREET, CHELTENHAM.)

According to the results of our examination this agreeably effervescent water is made with perfectly clean and pure distilled water On evaporation a residue of potassium carbonate was obtained which gave absolutely no sign of organic contamination. Calculating the salt present as bicarbonate of potassium the amount was equal to just under 15 grains per pint. The preparation of the water is evidently conducted with great care as we could get no *evidence of impurities* Sparkling Kalitzer affords a very agreeable way of administering an alkaline water when alkaline treatment is *indicated, as in gouty and rheumatic* conditions.

OFFLEY'S "DUKE" VERY OLD PORT

(OFFLEY FORRESTER AND CO., 66, MARK-LANE, LONDON, E.C.)

This is a well-matured, delicate, tawny wine. Analysis gave the following results: alcohol, by weight 18·08 per cent., by volume 22·18 per cent., equal to proof spirit 38·87 per cent.; extractives, 7·69 per cent.; mineral matter, 0·19 per cent.; fixed acids reckoned as tartaric acid, 0·18 per cent.; volatile acids reckoned as acetic acid, 0·09 per cent.; and sugar, 5·27 per cent. The analysis shows for port wine a minimum of sugar, extractives, and alcohol. This indicates a wine that has been long matured. The bouquet and flavour are excellent. The wine is exactly opposite in character to what is called a "heavy" and "heady" port. We believe it to be a pure and genuine wine.

ROBB'S SOLUBLE MILK FOODS

(A. ROBB AND CO., 79, ST. MARTIN'S-LANE, LONDON, W.C.)

According to our analysis these foods exhibit a chemical composition consistent with the physiological requirements of infant life Both foods are free from starch or cane sugar. Food No. 1, *which is intended for the use of* infants for the first four months of life, exhibits the following composition: moisture, 3·80 per cent.; fat, 18·00 per cent.; proteid, 13·67 per cent.; mineral matter, 2·10 per cent.; and carbohydrates, 62·43 per cent. The carbohydrates consisted of milk sugar with the hydrolysed products malt sugar and dextrose. The food is, therefore, largely soluble and, as a matter of fact, we found that over 70·00 per cent. was soluble in cold water. The amount of fat is satisfactory as is also that of the mineral matter containing phosphates. Food No. 2 contains a larger proportion of soluble sugars but is free from starch and cane sugar. No less than 83·60 per cent. of the food proved to be soluble in cold water. The larger proportion of carbohydrates necessarily reduces the percentage amounts of the other elements. Analysis gave the following results: moisture, 3·00 per cent.; mineral matter, 2·00 per cent.; fat, 4·80 per cent.; proteid, 7·60 per cent.; and carbohydrates, 82·60 per cent. The proportion of carbohydrates might, we think, be reduced with advantage and that of the fat and the proteid correspondingly increased.

KRESOPHEN.

(Willows, Francis, Butler and Thompson, Limited, 40, Aldersgate-street, London, E.C.)

We find that the statement in regard to the percentage of pure cresols in this preparation is correct. Thus on acidifying the preparation (which is alkaline) with hydrochloric acid the cresols separated to the extent of half the volume of the original fluid. This compound cresol is evidently prepared from materials of good and pure quality. It is free, for example, from inert tar oils and we can quite believe the statement that its bacteriological efficiency is superior to that of carbolic acid since cresols combined with alkali are known to be so and, moreover, they are less poisonous than is phenol.

ALL-MALT STOUT (GROUSE BRAND).

(Michell Goodman, Young, and Co., Stamford Hill Brewery, London, N.)

Nowadays it is refreshing to learn of instances in which malt liquor is really made from malt and we believe such to be the case with this stout. On analysis the following results were obtained: alcohol, by weight 4·62 per cent., by volume 5·78 per cent., equal to proof spirit 10·13 per cent.; extractives, 7·53 per cent.; and mineral matter, 0·33 per cent. This malt liquor contains an excellent proportion of nourishing constituents, as is evident from the amount of extractives which contain, moreover, just over 10 per cent. of proteid. The mineral matter was rich in phosphates found in malt. The stout was in good condition, free from excessive acidity, and satisfactory to the taste. It contained no substitutes.

CAPE HERMITAGE WINE.

(E. Westmacott and Co., 150, Leadenhall-street, London, E.C.)

Undoubtedly good and wholesome wines are produced in Cape Colony; they are, at least, the genuine fermented juice of the grape and they also possess distinct merit from the point of view of flavour and bouquet. It is, of course, an error to take as a standard for all wines the wines of France, just as it would be to regard all cigars from the point of view of the Havana crops. Cape Hermitage Wine is of burgundy type, somewhat full and fruity, with a slightly bitter flavour. Chemically speaking, it should be dietetically sound, as in particular both the sugar and the acid are almost negligible quantities. This will be seen from the following analysis: alcohol, by weight 11·62 per cent., by volume 14·37 per cent., equal to proof spirit 25·18 per cent.; extractives, 2·58 per cent.; mineral matter, 0·23 per cent.; sugar, 0·15 per cent.; fixed acids reckoned as tartaric acid, 0·30 per cent.; and volatile acids reckoned as acetic acid, 0·078 per cent. The wine possesses the invigorating qualities characteristic of wines of burgundy type.

CAILLER'S SWISS MILK CHOCOLATE.

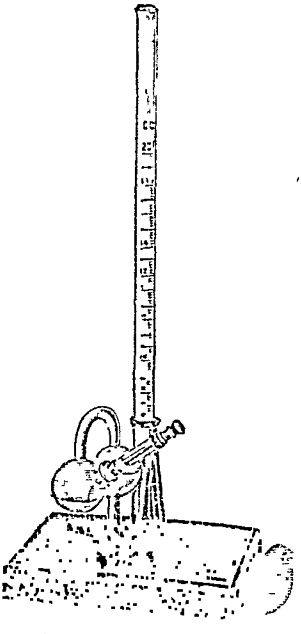
(Ellis and Co., 15, King-street, Cheapside, London, E.C.)

Some amount of proof that this chocolate is prepared with milk is afforded in the fact that it contains nearly 30 per cent. of fat, associated with the proteids of both milk and cocoa. Part of the fat is of course butter fat and part cocoa fat. The moisture amounted to 1·30 per cent. and the mineral matter to 1·0 per cent. This milk chocolate is evidently prepared from excellent materials and the flavour is particularly satisfactory. The preparation may be used conveniently for preparing a cup of hot chocolate.

New Inventions.

A NEW APPARATUS FOR THE ESTIMATION OF UREA.

The instrument shown in the illustration has been designed with a view to facilitate the estimation of urea for clinical purposes by means of the hypobromite method. The novelty consists in measuring the nitrogen by means of a column of water which rises in a graduated tube instead of measuring it by the volume of fluid displaced, as is done in previous ureometers. The glasswork, which is composed of two bulbs and an upright graduated tube, is in one piece. The outer bulb is for holding the hypobromite solution and in it the nitrogen is generated. The other bulb contains distilled water, coloured, if need be, with, say, three drops of red ink. This fluid will, when the bulb is full, be above the level of the lowest reading in the upright stem and when the nitrogen is given off by the action of the hypobromite in the former bulb it passes over and displaces a corresponding volume of water which rises in the graduated tube. In addition to the glasswork there are provided a perforated india-rubber stopper which fits into the mouth of the outer bulb and a small vulcanite syringe similar to those used for hypodermic purposes, with a mark on the stem of the piston to indicate when one cubic centimetre of fluid has been expressed from it. The indicating fluid is introduced into the long upright arm to the level already indicated. This may be allowed to remain permanently. In the next place from five to ten cubic centimetres of freshly made hypobromite solution are poured into the outer bulb and the stopper is firmly inserted. The syringe being then quite filled with the urine to be examined is inserted in the opening in the stopper. The nozzle of the syringe fits tightly into the opening so as to prevent the escape of any nitrogen. The reading on the graduated tube having been noted in order to identify the starting point of the rise, the piston of the syringe is slowly pushed inwards until the mark on the stem indicating one cubic centimetre of fluid expressed comes flush with the barrel. The empty syringe with the piston in the above position is left *in situ* and the instrument is gently rotated from side to side catching hold of the arch above. It is therefore unnecessary to touch the bulb containing the mixture evolving the gas after the urine has been introduced. When the evolution of nitrogen ceases the apparatus is left at rest for a minute or two in order to cool and a second reading is taken. The difference between the two readings less one cubic centimetre for the fluid injected from the syringe gives the volume of the nitrogen evolved, from which the weight or percentage of urea is obtained from a table in the usual way. When the estimation is completed the syringe and stopper are withdrawn and the indicating fluid falls back to its original level. With this instrument the froth causes no trouble, even if a little passes over into the second bulb. This is a decided advantage in dealing with albuminous urines. Messrs. Alexander and Fowler, surgical instrument makers, of Liverpool have made the instrument and supply it.



William G. Little, M.B. Edin

Great Crosby, near Liverpool.

THE LANCET.

LONDON: SATURDAY, FEBRUARY 11, 1905.

The Building By-laws.

THE subject of physical deterioration, or rather of physical inefficiency, is so much before the public mind at the present moment that almost every factor in our social life is by turns held responsible for the lack of physical fitness among the poorer classes and in this general ebullition of public sentiment the building by-laws have come in for, perhaps, more than their fair share of attention. As we recently pointed out in the Public Health section of our Annus Medicus, there is a tendency to insist that the reason above all others why the rural districts are becoming largely depopulated is the alleged prohibitive cost of building cottages to comply with the requirements of local by-laws. To those who are familiar with all the economic and social forces making for the exodus from country to town this by-law question seems hardly worth discussion in connexion with the subject. But as the lay press has been somewhat diverted from the real issue by Mr. Justice GRANTHAM'S alleged failure to comply with the one solitary provision of the by-laws, that detailed plans of cottages about to be built must be submitted to the local authority for approval, it may be useful to state briefly the facts relative to building by-laws in rural districts generally. In the first place it has to be pointed out that in something like 40 per cent. of our rural districts there are no building by-laws whatever in force and we are not aware that anyone has attempted to demonstrate that in such districts where there are no restrictions on building the population is increasing. It may also be added that the adoption of any by-laws whatever relative to building is an entirely voluntary matter, so that district councils wishing to befriend the local jerry builder are quite at liberty to do so. These facts do not appear to be appreciated generally. It is not quite clear to us which special provisions of the by-laws those who write so voluminously concerning them wish to keep and which they desire to relinquish. For instance, are they anxious to build houses on damp sites without drainage and without a damp-proof course and are they wishful to be entirely free from all restraint in the construction of cesspools and wells sunk in a pervious formation? Do they, too, seriously urge that houses shall be indiscriminately crowded together without light, air, or ventilation, and without any open space in connexion with each house? Is it their object at this juncture to recommence the erection of slums and hovels which it has been the pride of the latter half of the nineteenth century to have removed in large part? It would be well if those who wish to do away *in toto* with building by-laws were to inspect the dwellings in our poorer rural districts in a critical spirit. They might talk to the occupiers and encourage them to show the defects of their dwellings, with the floors rotten from damp, the papers peeling off the walls from a similar cause; low, leaky roofs and defective light and ventilation; pervious, filthy cesspits and pervious and imperfectly protected wells. These are some of the conditions which may be found in all parts of the country and those persons who are endeavouring to perpetuate them and to erect similar structures at the present day are the enemies of sanitation. It is earnestly to be hoped that the Local Government Board, which is sometimes in need of being reminded that it is the central *health* department of the State, will show itself proof against lay social pressure from without. In any circumstances it might be well, seeing that Mr. LONG has already heard the case from the landowners' point of view, if medical officers of health were to seek an interview with him by way of equalising the pressure already exerted upon him in one direction. But although we are strongly opposed to any interference with so much of the by-laws as relate to health, we are quite willing that the restriction relative to construction and to the prevention of fire should where practicable be relaxed and in this connexion we desire to draw attention to a letter from Dr. FRANCIS T. BOND which appeared in the *Times* of Jan. 19th.

Dr. BOND contends that the distinction which obtains in the matter of by-laws between "urban" and "rural" districts is in some degree illogical. This contention is quite sound and for the simple reason that large parts of many "urban" districts are really quite rural in character, while the conditions which obtain in some of the larger villages, in "rural" districts, or in "rural" districts abutting upon towns are, to all intents and purposes, urban in nature. In other words, there is ample room for the application of both the urban and the rural series of by-laws in the same sanitary district. It does not, however, appear to be known generally that it is now the practice of the Local Government Board, when local authorities apply for sanction to adopt either the urban or the rural series of building by-laws, to invite such authorities to reconsider the application with the view of determining whether the whole of either series is applicable to the whole district or whether there may not be parts wherein the new rural code will suffice and other parts where a modification of the urban code is not called for. It is, too, observed in the introduction to the new rural model of the Local Government Board that the series in question "contains no clauses dealing with questions of stability or the prevention of fire, or with the level, width, and construction of new streets" and the district council is invited "to carefully study the clauses and select those that are appropriate to the needs of the district or the portion of it under consideration." We would strongly urge all those who are seriously interested in the discussion as to the building by-laws to invest 6*d.* with Messrs. EYRE and SPOTTISWOODE and to secure a copy of this new model code. It is, we believe, possible under this series, or some variation thereof, to erect wooden buildings in rural districts. But Dr. BOND further suggests that the distinction as regards by-laws should be established not between urban and rural districts but between "detached and non-detached houses." While allowing very considerable latitude with respect to detached houses the by-laws should, he says, insist in the latter case "that such agencies as fire, wind, rain, and infection shall when affecting one house have as little chance of damaging the inmates of the house or houses connected with it as possible, and that in regard to the disposal of solid and liquid refuse each house shall be as independent of its neighbour as it is practicable to make it." This suggestion is one with which a large number of medical officers of health will agree, but a difficulty arises with regard to the latitude to be allowed in the case of detached houses. So long as a house is detached, well and good, but it would be necessary in order to perfect Dr. **BOND'S** suggestion that the detached house should remain so and the letter by Mr. **DOUGLAS ALLPORT** in the *Times* of Feb. 7th does not in our view meet this difficulty. There are places in large towns where the houses were once detached but have been since built on to in such fashion that what was once a suburban road of detached villas is now a street of continuous bricks and mortar. This is a contingency that will have to be provided against in all rural districts which are within the sphere of the probable expansion of large towns and in this connexion regard will also have to be had to the width of roads.

It has been suggested that all by-laws should be done away with and that the essential provisions relating to health which they contain should be embodied in a statute applicable alike to town and country. It is thought by some that there would be thus less interference with individual liberty. While seeing much in this proposal we hesitate to advocate it as a practicable measure at the present time, as we think that certain of the restrictions which are contained in the London Building Act would press somewhat heavily on rural districts; nor do we think that what is suitable for the country would suffice for the metropolis. As we opened this article with a reference to physical deterioration, we may fittingly close it by quoting recommendation No. 6 of the report of the Inter-departmental Committee on Physical Deterioration which is as follows:—

> *Building and open spaces.*—Local authorities in contiguous areas which are in process of urbanisation should coöperate with a view of securing proper building regulations, in furtherance of which end the making of building by-laws to be approved by the Local Government Board should be made compulsory on both urban and rural authorities; attention should also be given to the preservation of open spaces with abundance of light and air. By the use of judicious foresight and prudence the growth of squalid slums may be arrested, and districts which hereafter become urbanised may have at least some of the attributes of an ideal garden city.

The Care of the Feeble-minded.

THE problem of the care of the feeble-minded may be said first to have received attention on anything approaching a general scale in Europe and America towards the middle of the last century. In France the attempt to deal with this question may be traced to the beginning of that century and that country has been called the birthplace of the new education as it applies to the mentally defective class. Switzerland is another country which earlier than most occupied itself with the welfare of such defectives, being no doubt largely prompted thereto by the wretched condition of the cretins in its valleys. It is true that isolated efforts to collect the feeble-minded, together with the homeless and the outcast, for the purpose of care and supervision can be traced to much earlier dates but the general movement is associated with the period mentioned. In ancient times it is well known that the congenitally weak-minded were either destroyed outright or allowed to perish, being deliberately exposed to the risk of death, unless, perchance, they were tolerated for the sake of diversion. The drastic methods of the ancients find a milder modern counterpart in suggestions for the asexualisation of the mentally defective, suggestions which have already in a limited way been put into practice in the United States. In the Middle Ages the feeble-minded appear often to have wandered unmolested, being regarded with a certain superstitious reverence ("les enfants du bon Dieu"), and doubtless some of the fools and the jesters of mediæval times were recruited from this class. The village "fool" is still to be found, although there has of late years been a growing tendency to sweep all such feeble-minded persons into asylums for the insane, which is undoubtedly a mistaken course.

All schemes for dealing with the feeble-minded are necessarily based upon their classification and also upon the fact that cure does not take place but that even the best of them require a certain amount of supervision at the expiration of the period of training. For practical purposes these defectives may be classified as idiots and low-grade imbeciles, unimprovable or improvable in but slight degree, and mainly in self-help; imbeciles of higher grade, capable of being trained to such a degree as to be partially self-supporting; and the mentally feeble, capable of training to the extent of being self-supporting. The needs of the first class are met by the Idiots Act of 1886, which permits the detention of idiots and imbeciles in special institutions. These, however, are far too few, large areas of the country being unprovided for. In default of special institutions these cases, as well as many of the trainable classes, are relegated to workhouses and asylums where they are totally out of place except, perhaps, in those rare instances in which it has been deemed worth while to make separate provision for them. Too often such children are found scattered about asylum wards where their presence is a source of irritation to the insane and is apt to give rise to degrading practices. It is desirable that it should be made incumbent on county councils to provide accommodation for this class which could be cared for on a simpler and cheaper scale than that required in the case of the insane. It is, however, when we come to consider the second and third classes, as defined above, of defectives that we recognise the inadequacy of the means at present available for their detention and training and the harm which in consequence results to society. Unfit for ordinary school education, turned adrift from home, these feeble-minded individuals wander about living as best they can. Their history is made up of vagabondage, larceny, incendiarism, and criminal assaults. Feeble-minded young girls are received in a state of pregnancy into charitable institutions; feeble-minded youths are consigned to prison and transferred to the nearest asylum, where an anthropometric examination reveals abundant and pronounced stigmata of degeneration.

At the Guildhall Conference held on Oct. 14th, 1904, a suggestive paper on the problem of the feeble-minded, with especial reference to the legal powers for their training and detention, was communicated by Mr. A. F. TREDGOLD. After referring to the provisions for detention in the Idiots Act of 1886 Mr. TREDGOLD pointed out that until the year 1899 there was no real attempt made to provide educational facilities for the mass of the feeble-minded. The Defective and Epileptic Children Act of 1899, which allowed local educational authorities to provide special classes and schools for these children, appears, like much other permissive legislation, to have resulted with occasional exceptions in failure. Nothing can illustrate this better than figures quoted in the paper to which we refer, supplied by the Education Board's inspector of special schools, from which it appears that educational facilities exist, in the shape of these schools, for 5909 children, whereas it is estimated that there are 81,314 feeble-minded children of school age in England and Wales. There are other defects in the Act, apart from its permissive character, to which attention is drawn and for which remedies are suggested. As regards powers of legal detention of the feeble-minded, whilst recognising the need for a considerable increase in the number of special institutions for the unimprovable, or but slightly improvable, imbecile, Mr. TREDGOLD advocates the permanent care in an industrial colony of all feeble-minded persons who are found after expiration of the training period to be incapable of self-support and all feeble-minded persons at large without proper control or proved guilty of offences against the law. A motion in these terms was carried unanimously by the conference. The county councils would be the natural authorities to provide and to maintain these colonies. With respect to the feeble-minded who have by training been rendered capable of self-support and are able to earn an honest living there are those who, taking an extreme view, would have these also permanently detained in the interests of society. It may be affirmed with considerable confidence that such a course would not be found practicable so far as this country is concerned. But that some degree of supervision of this class is highly desirable may be admitted. Mr. TREDGOLD suggests that this might be supplied by after-care associations and by the provision of voluntary boarding-houses and colonies, and the suggestion is worthy of consideration. A survey of the present position makes it evident that for an adequate solution of the problem of the care of the feeble-minded the powers already conferred by the law should be more widely utilised and ampler powers should be sought.

Medical Teaching in the Metropolis.

THE brief announcement of the recent change which has been effected by the Council of King's College, London, merits the thoughtful consideration of all who are interested in the development of the teaching of medical students in the metropolis. It will also affect those who are concerned in the growth of the University of London as a teaching university, since it cannot fail to have an influence upon the cherished scheme of centralisation. The change is that which was foreshadowed in the address by Dr. T. BUZZARD at the commencement of the medical session; it is the recognition of the possibility and desirability of making a complete separation in the curriculum between the earlier subjects which can be taught only in well-equipped laboratories and the later clinical subjects which necessitate attendance in the wards and the out-patient rooms of a hospital. It has long been felt that many inconveniences attended the attempt to undertake clinical work before the examinations in anatomy and physiology had been passed. The premature introduction of living interest has been thought likely to divert attention and to delay the acquisition of the amount of detail required by the examining bodies. On the other hand, in many branches of clinical work it is obviously undesirable that assistance should be rendered by those who have just quitted the dissecting room. The question is one upon which opinions differ. Older practitioners may still be found who cling to the idea that the student should spend every available moment within the walls of a hospital but modern teachers and nearly all members of the staff of the hospitals maintain that, apart from considerations of the safety of the patients, there is little or nothing to be [illegible] from perfunctory attendance without time for reading. Clinical observation must be combined with the judicious use of text-books and this combination is difficult, if not impossible, when examinations in anatomy and physiology are looming in the near distance.

Due recognition of these principles has doubtless influenced the Council of King's College in the step that has been taken. Hitherto matters of detail have been controlled by a medical board consisting essentially of teachers in the medical faculty and of the honorary staff of the hospital. With the projected removal of the hospital to Camberwell it was impossible for this arrangement to be continued and the Council, through Dr. BUZZARD, in October last announced a forthcoming change. This proposal has now taken shape in the division of the medical board, and consequently of the medical school, into two parts which will in future be completely distinct in everything except in their relation to the Council. In other words, the faculty for advanced medical study will have its own board and its own financial arrangements and in due season all its teaching will be conducted in connexion with the new hospital buildings. Similarly, the faculty for the preliminary and intermediate subjects will be controlled by a board composed of the professors of these subjects and its [illegible] will be distinct from those of the faculty for advanced medical study. The removal of the hospital has doubtless been the main reason for this separation of the two faculties but the division is one which will commend itself to all who have followed the trend of opinion of recent years. The University of Cambridge has demonstrated the possibility of this division of studies and of examinations, since undergraduates in medicine ordinarily receive the whole of their clinical instruction in London after they have passed the preliminary and intermediate examinations. The development of this system in the metropolitan schools has been hampered by the idea that there was some advantage in teaching all subjects in all schools and the costliness of this needless multiplication has long been apparent.

Coöperation and concentration have frequently been urged as affording a means of reducing the burden; these suggestions, however, have not been generally adopted, though there is abundant evidence that a change of opinion is gradually growing and that many of the smaller schools are already considering the possibility of freeing themselves from the expense of maintaining laboratories and dissecting rooms.

In every state of transition some hardship is experienced and it can scarcely be expected that concentration can be effected without protest from those who fear loss of occupation during the period of waiting for promotion to hospital appointments. This anxiety is, we believe, based on misapprehension. Development is not confined to the earlier branches of medicine, it has been making rapid strides in connexion with clinical work and it is more than probable that in the near future every hospital will be found able to supply numerous junior appointments for those who desire occupation and opportunity of demonstrating their powers of teaching or of prosecuting original research. Meanwhile the complete separation of King's College from King's College Hospital in this formation of two new faculties must be regarded as a bold move at the present juncture, since the result must be that each faculty must be self-supporting. The expenses of the clinical faculty are comparatively small but in the absence of endowment the faculty for preliminary and intermediate subjects can only be maintained by a process of concentration. It is evident that the Council of King's College believes that this concentration will be favoured by the step that has been taken. Whether this is only a preliminary step to an increased connexion between the College and the University of London remains to be seen.

Annotations.

"Ne quid nimis."

THE INTERNATIONAL CONGRESS OF MEDICINE, LISBON, 1906.

A meeting of the national committee of Great Britain and Ireland of the Fifteenth International Congress of Medicine to be held at Lisbon from April 19th to 26th, 1906, was held at the rooms of the Medical Society of London on Feb. 3rd. There were present, amongst others, Dr. F. W. Pavy (president of the national committee), Sir William S. Church, Sir Dyce Duckworth, Dr. D. Ferrier, Dr. J. F. Gordon Dill, Dr. H. Radcliffe Crocker, Dr. Boyd B. Joll, Mr. W. H. H. Jessop, and the honorary secretaries, Dr. Clive Riviere and Mr. D'Arcy Power. It was announced that the following gentlemen had undertaken to act as "rapporteurs" at the forthcoming Congress, as it was the wish of the Lisbon committee to make the "rapports" a special feature of the meeting: Dr. Stanley B. Atkinson, honorary secretary of the Medico-Legal Society and barrister-at-law, Spontaneous and Criminal Abortion in its Medico-Legal Aspect; Dr. A. K. Chalmers, medical officer of health of the city of Glasgow, the Administrative Control and the Technique of Public Disinfection; Mr. E. Treacher Collins, Ocular Tuberculosis; Dr. Ferrier, the Nature and Pathological Physiology of Tabes; Mr. K. W. Goadby, lecturer on bacteriology at the National Dental Hospital, the Treatment of Pyorrhœa Alveolaris; Dr. G. L. Gulland, the Classification, Origin, and Probable Rôle of Leucocytes, Mastzellen, and Plasma Cells; Dr. F. W. Mott, Cerebral Lesions in Psychoses of Toxic Origin; Mr. D'Arcy Power, Recent Advances in the Surgery of the Arteries and Veins; Dr. G. F. Still, the Spastic Affections of Childhood, their Classification and Pathogeny; Dr. J. F. Sutherland, Deputy Commissioner in Lunacy for Scotland, the Prophylaxis and Treatment of Habitual Criminals; and Mr. C. E. West, chief assistant in the aural department at St. Bartholomew's Hospital, Study of the Eleptogenous Action of Foreign Bodies in the Ear and of Post-nasal Growths. The subjects for the "rapports" were selected in every case by the executive committee at Lisbon. Sir Patrick Manson will open a discussion on Tropical Medicine. A letter was read from Messrs. Cook and Son containing a proposition to charter a first-class passenger ship to convey visitors to and from Lisbon, calling at Corunna, Vigo, and Oporto, and acting as a floating hotel during the Congress week. The suggestion was approved by the committee but Messrs. Cook and Son were desired to ascertain the exact position of the anchorage in the Tagus in order that inquiries might be made locally as to its suitability both from the point of view of the hygienic surroundings and of distance from the seat of the meetings of the Congress. Letters were read from Dr. J. C. Ogilvie Will and from Dr. F. J. Sutherland giving the results of certain inquiries which they had made in regard to the housing of those who did not wish to go by sea and to remain on the boat. It appeared from these inquiries that rooms could now be obtained at a moderate price at Netto's Hotel, Cintra, about 40 minutes by train from Lisbon. The hotel is well spoken of and the proprietor says that at present he has 16 bedrooms, most of which can be used by two persons. It appears imperative, therefore, that those who intend to go to the Congress and do not wish to depend on the efforts of the local committee to obtain lodgings should at once take the opportunity of reserving rooms. Delay is likely to lead to the same disastrous consequences as at Madrid.

"THE CAUSE AND PREVENTION OF APPENDICITIS."

Under this heading there appears in the *Nineteenth Century* for January an article which professes to have solved the problem of the etiology of appendicitis. The author of this communication strongly denounces the use of "Hungarian waters, aperient salts, and liver pills." He then remarks: "It is natural to ask what have aperient waters and salts to do with appendicitis? To that a very true answer is that the action of saline purgatives is to cause a flow of water through the intestinal canal. This passes off quickly, but alas! it leaves the solid portions to accumulate in the cæcum at the right side, near the appendix, where the small intestine ends and the large one commences. The solid portions left in the colon become more and more putrid, cause obstruction, and infect the appendix." The meaning of the above sentences is somewhat ambiguous but we conclude that it is intended to convey the idea that those individuals who habitually take laxatives to insure an action of the bowels are liable to fæcal collections in the cæcum which produce inflammation of the mucous membrane of the bowel and so cause appendicitis. We venture to express an emphatic opinion that there is no basis for this statement either on pathological or clinical grounds. Any practitioner who has had experience in the post-mortem room knows that the contents of the small intestine are liquid and it is not until the colon is reached that the fæcal matters become *solid*. It is most unusual to find solid fæcal accumulations in the cæcum; yet this condition is distinctly implied in the remarks which we have quoted above. Further, in post-mortem examinations of those who have died from appendicitis, although small concretions may be found in the appendix, no large mass is found in the colon as would be the case if the etiology which we are considering were the correct one. Such a causation of appendicitis is also contradicted by clinical experience. The age at which appendicitis usually occurs[1] is from ten to 20 years, which is not the period of life at which such purgatives are generally habitually taken. Again, constipation is more frequent among women than among men and the former are more addicted to the habitual use of purgatives, yet appendicitis is nearly four times as common in men as it is in women. It is certainly desirable to overcome constipation by natural means, notably by diet, if possible. But there are numerous cases in which artificial stimulus to the intestines is absolutely necessary and in such circumstances "aperient waters and salts" are most valuable remedies.

A LUCKY ESCAPE.

AT Southport police-court recently a grocer who had attempted to vary his stock-in-trade by importing a freshly killed pig from Ireland had a narrow escape. The pig, according to the defendant's evidence, which there was no reason to doubt, arrived at his place of business in good condition. A small portion of it was sold by him as fresh pork on the day of its delivery, a Friday, and on the Saturday, and some pieces were given by him to men in his employment. On the following Wednesday he found that the meat was high and in his defence he swore that he then refused to sell some to a customer. Two days afterwards, however, the remainder of the pig was still in his shop, where it was found in the course of his round by an inspector of nuisances in a putrid condition; an order for its destruction was obtained and a summons was taken out against its owner. There was one question only for the bench to determine, the condition of the meat and the responsibility of the defendant for its presence where it was being undisputed; that is to say, the magistrates were asked to decide whether or not it was exposed for sale as human food, the burden of establishing the fact that it was not there for such a purpose resting on the defendant. On the one hand it was proved that the meat was in the shop, in a tub, and that it was standing surrounded by other comestibles undoubtedly intended for sale as food, and it was also alleged by the prosecution but not admitted by the defence that there was a piece lying on the counter. As an answer to this the defendant swore that finding the meat was bad he put it in a tub by itself, intending to sell it for the value of the fat to a marine store dealer, and that he had had no opportunity of carrying out this innocent design before the inspector's appearance. There was corroboration as to his allegation that he was without experience in dealing with such goods and he explained the circumstance that the pork was covered with salt by saying that he had put salt on it in order to diminish the smell which it emitted. The awkward aspect of the case for him arose out of the fact that if he had really desired to be rid of so very offensive an addition to his other wares as a tubful of decaying flesh he could have placed it in the yard at the back of his shop and that its presence where it was was likely to be harmful to his ordinary business, apart from the risk of a visit from an inspector of nuisances. At the same time the condition of the meat was apparently so obvious that no one at all events was likely to buy it without appreciating the fact that it was in very bad condition, and having regard to all the circumstances the magistrates made use of a well-worn phrase and, allowing the defendant "the benefit of the doubt," dismissed the summons against him. Even after such an escape he must have gone home a poorer if not a wiser man and others in his locality who read of what happened to him in the full report accorded to the case by the local press may profit by his example. At least they should learn that persons who find themselves in the possession of foodstuffs wholly unsuited for human consumption will, if they are wise, do all in their power to place themselves forthwith beyond the reach of possible suspicion. The decision upon such an occasion is one of fact and, as has been stated above, when the other points have been proved the person charged has to show that the goods were not there to be sold as human food—that is to say, in this respect it is for him to establish his innocence and not for the prosecution to prove his guilt.

JANUARY AT HOME AND ABROAD.

THE month of January must have been a great disappointment and a source of great discomfort to all except the most robust who travelled south to escape the rigours of the coldest period of the year. Without going so far as to say that the cold and rough weather of January was unprecedented in the south of Europe it can safely be affirmed that it was the most severe during the present generation. Nor was the cold confined to any particular locality but while all the more sheltered spots naturally suffered the least none of the winter resorts escaped a temperature far below the normal, besides experiencing unpleasant falls of cold rain, sleet, and snow and a sky usually very cloudy or quite overcast. In studying the appended table it is seen that Nice and Biarritz each had a lower minimum temperature (recorded by the screened thermometer early in the month) than our own inland places of Bath, Nottingham, and London, while that at Florence was only one degree higher than at Bath and Nottingham and that at Rome just equal to London (St. James's Park). Even at Naples and Palermo there were several degrees of frost, while at Algiers and Lisbon the thermometer descended to within two degrees of the freezing point. At Naples frost was registered on seven nights, at Nice on ten, at Rome on 12, and at Florence on as many as 19. In London there were only 16 frosts, at Torquay two or three, and at Scilly none. The mean temperature for the month was highest at Algiers, Palermo,

[1] System of Medicine, by Professor Clifford Allbutt, vol. iii., p. 896.

and Lisbon but at all the other foreign resorts it was lower than at the Scilly Isles, Torquay, and Jersey; at Florence it was three degrees lower than in London and two degrees lower than at Nottingham, one of the coldest parts of England. At almost all the foreign stations the means of the minima were inferior to those on our own south-west coasts; at Florence the mean minimum was ten degrees lower than at Torquay and Jersey and 14 lower than at the Scilly Isles. The nights at Scilly were, in fact, much warmer than the combined day and night at Florence, had just the same temperature as the corresponding figure at Nice and Naples, and were within half a degree of that at Biarritz. The highest temperature of the month was recorded at Nice and occurred immediately after the severe cold at the beginning of the year. The average day at Rome and Biarritz had the same degree of warmth (49 degrees) as the Scilly Isles, while that at Naples just equalled Torquay. With regard to equability none of the continental resorts can compare with Scilly, Jersey, and Torquay, and few of them were as equable as Nottingham. The precipitation from the clouds, composed largely of sleet or snow, was only excessive at Algiers; in this country it was (except at Jersey) much less than during an ordinary January. At all the British stations the number of hours of sunshine was far above the average, Torquay and Jersey being particularly bright.

WOMEN INSPECTORS OF MIDWIVES AND WOMEN HEALTH VISITORS.

IF the regulations laid down by the Central Midwives Board under the Midwives Act, 1902, are to be carried out properly a considerable amount of work will have to be done in regulating, supervising, and restricting within due limits the practice of those midwives who may be certified under the Act. In large towns or country districts where there are many midwives engaged in practice it will hardly be possible for the medical officer of health adequately to perform these duties. In a report presented by its medical officer to the Durham county council the question of the appointment of women inspectors of midwives and women health visitors is considered. As the result of his inquiries Dr. T. Eustace Hill finds that in ten counties a woman inspector of midwives has been, or is about to be, appointed and in two others the necessity of such an appointment is recognised by the medical officer of health; in two a scheme is being prepared for the supervision of the midwives by the local medical officers of health acting under the county medical officer; in one the county medical officer recommends that the work should be carried out by an assistant medical officer; and in five counties so far no action has been taken in the matter. The chief duties of such women inspectors will be to see that the rules of the Central Midwives Board are duly observed by the certified midwives and that the registers and records as required by the Act are properly kept by the midwives, and, in addition, to exercise an educational influence on the older school of midwives whose knowledge of their duties is far from being as perfect as it might be. Obviously such women inspectors must not only themselves be certified midwives under the Act but should also hold a certificate of midwifery from one of the bodies recognised by the Central Midwives Board. The appointment of women health visitors has met with such marked success in Birmingham and other towns in which they have been appointed that it is to be hoped they will soon be at work not only in all towns but also in the country districts. The work of an inspector of midwives and a health visitor could in many instances be carried out by the same person, and there should be no difficulty in finding women sufficiently well trained to fill such posts. The work of a woman health visitor would mainly consist in calling at the houses of the poor and in giving advice as to the importance of cleanliness, fresh air, and ventilation, as to the feeding and clothing of young children, as to the prevention of the spread of infection, and many other matters which affect the health of the poorer classes. In Birmingham and St. Helens the health visitors are supplied with a list of the registered births and they visit the houses in the streets inhabited by the poorer class with a view to see if the infants are properly fed. As Dr. Hill points out, it is a melancholy fact that while during the last 20 years the general death-rate has progressively declined the infantile mortality has not shared in the decline to any appreciable extent. Since the infantile mortality has not been influenced by the improvement in the sanitation and in the water-supply which has taken place in most of the larger towns during this time it must be due to other conditions which so far have undergone no alteration. There can be no doubt that the most important of these is the gross ignorance which prevails amongst the poor as to the proper method of feeding their young infants. Women health visitors could do much to train poor mothers in the management and care of their young children. By the delivery of "Health Talks" in elementary schools they could also impress upon the children attending them the value of fresh air, ventilation, and personal cleanliness. Such "Health Talks" already are being given in some of the elementary schools throughout the country with a very marked improvement in the condition of the children. We hope that the Durham county council will adopt Dr. Hill's suggestion to appoint two ladies as inspectors of midwives and health visitors and that other county councils will see fit to adopt the same means of insuring the efficient working of the Midwives Act and of lessening the infantile mortality which in many of the larger towns of the country is still most deplorably high.

PNEUMOCOCCIC MEMBRANOUS BRONCHITIS IN A CHILD.

AT the meeting of the Société Médicale des Hôpitaux de Paris on Dec. 9th, 1904, M. Menetrier described a case of membranous bronchitis in a child, aged two years, which in consequence of the rarity of the disease at this age apart from diphtheria is important. The child was taken to hospital on March 1st, 1904. For two months he had expectorated arborescent membranes after fits of coughing and suffocation. There were two other children in the family, aged respectively three and four years, who were in good health. The patient contracted bronchitis when he was eight days old after exposure to cold and the attack lasted for more than three months. At the age of four months he had another attack which lasted the same time. In January, 1904, he had a third attack which, like the preceding ones, was attended by fever and cough without expectoration. But the cough was more severe and on Feb. 7th he expectorated, after a violent fit of coughing in which suffocation seemed imminent, a mass of whitish membranes which on being spread out in water were found to consist of ramified tubes. Since that time fits of coughing occurred nearly every day but only every three days were membranes expectorated. The child lost appetite and wasted. On examination he was pale and thin. The throat was normal. The upper two-thirds of the left chest in front and behind were slightly dull on percussion and the breathing there was bronchial and accompanied by large subcrepitant râles. The temperature was normal. Iodide and inhalation of creasote in boiling water were prescribed. When he was seen again on March 5th he was much better, the cough was diminished, and he was recovering appetite. He had expectorated membranes on March 1st but not since and he had had no attacks of suffocation. The dulness and the bronchial breathing were still heard but no râles. No more membranes were expectorated and after two months he was said to be quite well but no further opportunity for examination was given. The membranes produced at the first examination looked somewhat like cooked macaroni and formed a ramified mould of the bronchial tree of a whole pulmonary lobe without any central cavity. The membrane was firm, like that of diphtheria. It contained pneumococci in large numbers and yielded the pneumococcus in pure culture. A mouse inoculated with it died from pneumococcic septicæmia. The membrane was composed of stratified layers of fibrin, leucocytes, and cubical epithelial cells of the type found in the capillary bronchi. Nowhere was there any ciliated epithelium of the type found in the larger bronchi. Evidently the capillary tubes were the seat of the disease.

MAXIM GORKY ON UNDERGROUND BAKERIES

THE arrest, on what appears to be but a trivial pretext, of one of the most eminent men of letters ever produced by Russia naturally provokes protests from all parts of the civilised world. In his realistic writings Maxim Gorky describes what he has himself endured. Occasionally there are details given which show how much there is to be done before Russia can compare favourably with Western nations in regard to sanitary matters For instance, in his sketch entitled "Twenty-six and One" he relates that in his youth he worked in a baker's shop where 26 toilers were sweated to enrich one master baker. These 26 "living machines" were cooped up in the sludge and murk of a damp cellar. There they kneaded dough to make cracknels and biscuits. The windows of the cellar were coated with flour dust inside and protected outside with wire netting. The light could not penetrate and as for the air these windows, such as they were, stood close to, and on the same level as, a manure heap and pit the wall of which had grown green with damp and foulness. In England the law declares that no bakehouse shall be near any open drain whatsoever The workers carried particles of manure on their boots into the evil-smelling underground bakery. This is how Maxim Gorky describes the bakehouse :—

> ... . . . is stone box under the low
> noke, black, and coated with
> vithin the thick walls which
> w. We were wont to rise at
> night's sleep and at six we
> to shape cracknels of dough
> prepared for us by our mates who had toiled while we were sleeping And thus the live-long day, from early morning till ten at night, we kept it up. ... . We kept rolling out dough and making cracknels, moistening them with our sweat We loathed the very sight of our handiwork, turning from it with nausea, nor would we ever eat of anything that left our hands, preferring to the cracknels coarse black bread.

Evidently there were no inspectors of nuisances in that part Nor was there any organisation among the journeymen bakers or Maxim Gorky would have been paid more than his board and the munificent sum of 5*s*. per month. If such are the conditions of labour it is not surprising that the death-rates of Russian towns are abnormally high.

OVARIOTOMY IN YOUNG CHILDREN.

DR. J. Hope Reford has recorded in THE LANCET of Feb. 4th, p. 322, a very interesting case of ovariotomy undertaken in a cottage on a girl, 11½ years of age. The tumour, which was growing from the left ovary, contained about one and a half pints of slightly blood-stained fluid and was a dermoid cyst. The child made a good recovery. Cases of ovariotomy in young children are not very uncommon and Mr. J. Bland-Sutton in his work on Surgical Diseases of the Ovaries has published a table of 100 cases of ovariotomy in girls under 15 years of age, and of these no less than 89 were younger than the patient in the case recorded by Dr. Reford. 41 of the cases were operated on for simple cysts and adenomata of the ovary with three deaths, 38 for dermoid tumours with five deaths, and 21 for sarcomata with seven deaths. In seven of these latter patients the subsequent progress of the case has been ascertained; four of them died from recurrence of the growth within a year, one was alive and in good health a year later, one two years later, and one died two years after the operation, the cause of death being uncertain. Since the publication of these tables other cases have been recorded. Mr. F. S. Eve has successfully removed a suppurating ovarian cyst measuring one and a half inches in diameter from an infant 22 months old. The youngest child from whom an abdominal cystic tumour has been removed would appear to be a case recorded by Mr D'Arcy Power who operated successfully for a simple cyst of the ovary on an infant only four months old. Dr. John Campbell operated successfully upon an infant only seven months old and removed a dermoid tumour growing from the left side Dermoid tumours appear to be especially frequent in young children and ovarian sarcomata are met with more frequently before puberty than at any other period of life but as Mr Bland-Sutton points out there is no example of a papilliferous or parovarian cyst amongst the cases collected by him. Mr. Alban Doran has described small cystic tumours in the ovaries of the fœtus and in a child born alive at the seventh month he found a sarcoma of the ovary. No Graafian follicles could be detected in this case. The very successful results which usually follow such severe operations in young children are no doubt in part to be explained by the absence of any mental apprehension as to the result of the surgical interference It is interesting to note how often in the diagnosis of such cases the condition has been mistaken for one of tuberculous peritonitis and this is especially liable to be the case when the pedicle of the tumour has become twisted.

SOILS AND THE DISTRIBUTION OF DISEASE.

ALTHOUGH it is generally admitted that there is an intimate connexion between the health of a locality and the nature of the soil found within its boundaries the character of the relationship is decidedly obscure. This obscurity will, perhaps, not be diminished by a report which Mr. H. B. Woodward, F R S, contributes to the recently issued "Summary of Progress of the Geological Survey of the United Kingdom and Museum of Practical Geology," though his conclusions are not the less valuable on that account. It has been customary to study the distribution of diseases with the help of small geological maps—e g., those on a scale of four miles to an inch alluded to by the late Mr. Alfred Haviland in his article dealing with this topic which appears in Vol I of Allbutt's "System of Medicine." In his account of certain investigations into the constitution of the soil at the famous Rothamsted estate, whence have emanated so many scientific results of the greatest importance to botany and agriculture, Mr. Woodward incidentally refers to certain points in the interpretation of the maps published by the Geological Survey which are worthy of the attention of medical topographers. Originally, it was assumed that the soils and the subsoils were the result of the decomposition, through atmospheric agencies, of the rocks directly below them and the maps marked out only the areas in which the various rocks came to the surface or "outcropped." This was fairly satisfactory in Cornwall and Devon where the survey first began operations but as the work extended to other districts it was found that the ground was largely covered by superficial deposits increasing in amount on the whole towards the north of the country. To these deposits, relics of the ice-sheet which once covered the land, the term "drift" was applied. For a time they were ignored but when it was found that the "drift" covered great areas and that it was often 100 feet thick or more it was realised that maps which did not take account of its existence were misleading. A correct representation of the "drift" was found to be impracticable on maps of even a scale of one mile to an inch and it was therefore necessary to construct maps of six inches to one mile. Maps of this latter kind can be consulted at the Geological Museum at Jermyn-street and it will be obvious from what has been said above that only such maps are worthy of serious consideration in attempting to elucidate the dependence of pathological conditions upon the geological features of a given district. Nor do the difficulties of the problem end here. The maps show only the nature of the subsoil and Mr. Woodward states that "they cannot be taken as indicating in more than a general way the actual distribution of soils." He shows that soils are far from being "sedentary" and that those derived mainly from one formation may be transferred as the results of landslips, downwashing, or the action of the wind to the surface of another and may thus have no simple relation to the underlying strata. We do not suppose that anyone will have the temerity to dispute Mr. Woodward's contentions in a matter of this kind and can only hope that he or some other worker on the survey may in a subsequent report throw some much-needed light on this intricate subject.

BLOOD PRESSURE IN MAN.

ON Feb. 3rd, at the Royal Institution, Professor T. Clifford Allbutt, assisted by Dr. W. E. Dixon, demonstrator of pharmacology at Cambridge, gave a lecture on Blood Pressure in Man. The first part of the lecture was occupied by a sketch of the physiology of the subject. It was pointed out that as fluids are incompressible elasticity is obtained by the structure of the arteries and that the aorta, being larger in proportion than other arteries, acts the part of a reservoir, as does the air bag of the bagpipes, to equalise the pressures. The construction of the arterial tree is such as to facilitate the distribution of the blood with the least disturbance of pressures. Nevertheless, he showed by the effects of muscular exertion; cold baths, and so on, that the variations of pressure in man are large and herein differ from the stability of the temperature of the body. But a small fraction of the heart's energy is employed upon the velocity of the blood, the chief expenditure being in overcoming friction. The friction depends on two factors—the dimensions of the vessels and the viscosity of the blood which is about four times that of water. Dr. Dixon exhibited with the lantern a rabbit's heart, under artificial circulation, attached to a lever and registering its curves upon a smoked glass. To this heart drugs were applied—adrenalin, atropine, pilocarpine, nicotine, and so forth—by which the pressures were modified. The various instruments for registering pressures in man were then exhibited—three of them in action—and projected upon the screen. The lecturer then proceeded to the pathological applications of these principles, illustrating them in shock and collapse, under chloroform, hydrocyanic acid poisoning, the nitrites, and so forth. Dr. Dixon showed the action of such changes on the screen. Diagrams were exhibited of the remarkable observations of Kocher and Cushing on the enormous increase of pressures set up during compression of the brain in order to counteract the emptying of the vessels of the medulla by the intracranial pressure and thus the danger of bleeding in apoplexy had been made manifest by those observers. Finally, the importance of integrity of the arterial mechanism was insisted upon and the effect of toxic matters, of hard labour, and of senile changes was illustrated. The tendency in many persons to rises of arterial pressure in middle life was shown as well as the injury done to the vessels thereby. As these rises, if taken in time, may be counteracted the lecturer urged upon all persons between 45 and 55 years of age to have their arterial pressures estimated by their physicians every four or five years in order that this peril to health and life may be averted. Such rises may occur also in old persons in whom the arteries have undergone senile degeneration and in them are the more perilous, but in most cases, if discovered in time, they can be readily counteracted.

"DR." BELL AND THE POST-OFFICE.

WE are constantly being asked whether we can do anything to stop the circulation of a dirty little pamphlet that continues to be sent out by a quack living in Wardour-street under the name of "Dr. Bell." Some few years ago "Dr. Bell's" name was "Henry Walters" and some few years before that again he was "Dr. Rae" or "Ray," who possessed an American doctor's degree. We shall be obliged if any of our readers who may receive one of "Dr." Bell's pamphlets will forward it to us, *together with the wrapper or envelope* in which it may have been sent, at as early a date as possible after its receipt.

THE GILLSON SCHOLARSHIP IN PATHOLOGY.

THIS scholarship is of the annual value of £90 (tenable for one year) and was founded in accordance with the will of the testator, William Edward Gillson. The scholarship is open to Licentiates of the Society of Apothecaries of London, or to candiates for the Society's diploma, who obtain such diploma within six months of their election to the scholarship which is awarded for the encouragement of original research in connexion with any branches of pathology. Candidates must be under 35 years of age. The holder is eligible for re-election provided that he satisfies the adjudicators that he has carried out well-directed research during his year of tenure; but in no case can the scholarship be held by the same person for more than three years. Candidates competing for this scholarship are required to send in their names, with testimonials, by Feb. 28th, to Mr. Frank Haydon, secretary to the court of examiners.

TUBERCULOSIS IN NOTTINGHAMSHIRE.

WE have received a copy of the annual report of the medical officer (Dr. Henry Handford) to the county council of Nottinghamshire for the year 1903. The report has been most carefully compiled and presents some interesting information. The most striking feature concerning the mortality statistics is the fact that for the first time the rural death-rate exceeds the urban. This is remarkable and is the more accentuated by the fact that the infantile deaths are more numerous proportionally in the urban than in the rural districts and, moreover, account for more than one-quarter of the total deaths. The altered relative position of the urban and rural death-rates appears to be mainly due to a decrease in the urban rates; the rural rate only increased 0·3 per 1000. Dr. Handford asserts that it is difficult to avoid the conclusion that the urban districts are reaping the advantage of their larger expenditure in measures of water-supply and general sanitation. The number of deaths from pulmonary tuberculosis was 262, or 0·88 per 1000 of the population. In the urban districts there were 139 deaths, or 0·8 per 1000, and in the rural districts 123 deaths, or 1·01 per 1000. The deaths from tuberculous disease of other organs than the lungs were 150 for the whole county, or 0·5 per 1000 persons living. In the urban districts there were 93 deaths, or 0·53 per 1000, and in the rural 57 deaths, or 0·46 per 1000. These figures show the strange result that in 1903 in the county of Nottingham pulmonary tuberculosis was more fatal in the rural districts than in the urban. "Other tuberculous diseases" were only very slightly less fatal, the balance in favour of the rural districts being only 0 07 per 1000 Dr Handford publishes an interesting table showing the average death rate from pulmonary tuberculosis for the past ten years in the various urban and rural districts of the county It is proved that the death rate from this disease has not been materially influenced by the geological character of the country, the districts most severely affected being of varying geological nature Conditions of housing and sanitation appear to have been of most importance These statistics can only be taken as being suggestive , investigations carried out over larger areas and over many counties would be required before any definite conclusions could be drawn from them

THE TREATMENT OF PULMONARY TUBERCULOSIS BY CYLLIN

Mr W C Lodwidge informs us that he has treated eight cases of pulmonary tuberculosis by inhalations of cyllin Some of the patients were in an advanced stage of the disease In every case some improvement was obtained as evidenced by a steady increase in weight a diminution in the quantity of the sputum, and relief from cough and night sweats Mr Lodwidge believes that the drug acts primarily by destroying the pyogenic organisms and secondarily by exercising an action on the tubercle bacilli He has made a careful systematic study of the various drugs which have from time to time been prepared as "inhalants for the treatment of pulmonary tuberculosis He has also calculated the relative bactericidal value of some of these drugs when tested against vigorous cultures of the bacillus typhosus He finds that cyllin is 12 times as powerful as carbolic acid Further, cyllin may be inhaled without any deleterious results The number of cases recorded by Mr Lodwidge is small but the results which he has obtained warrant a further trial of the remedy and observations carried out on a more elaborate scale than has been as yet accomplished

SCHOOL DRESSING ROOMS

AMONG many matters of interest to be seen at the Exhibition of School Building and Furnishing Appliances open in the great hall of the University of London during the continuance of the Conference on School Hygiene organised by the Royal Sanitary Institute of Great Britain, few bear more emphatic testimony to the extent and character of modern improvements in the surroundings of the schoolboy than the plans lent by Mr Sargant to illustrate the changing and dressing rooms now in course of construction at Oakham Without repeating Mr Kipling's substantives we may use one of his adjectives without offence and may admit that the boy who comes in from football is always muddy—and generally wet If his clothes are to be distributed over his bedroom there will be a bad time for somebody in the way of collecting and drying them and the general state of that bedroom will not be improved At schools of course, the consequent difficulties are raised to the nth power and Mr Sargant has been equal to the emergency in devising contrivances for meeting them His plans show an arrangement under which each dormitory for 16 boys has attached to it a changing and washing room devoted solely to these purposes Every such room contains a central range of 16 basins supplied with hot and cold water and discharging into a suitable channel Benches run down each side of the room and behind these are 32 drying lockers, each 1 foot 3 inches by 11 inches by 2 feet 6 inches into which football things must be put Pegs for hanging up clothes are fixed over each locker Sitz and shower baths are provided in the same room, supplied with water which can be made warm but not hot There are also depositories for shoes and no boots are allowed to be taken into the dormitories The general effect is to furnish all necessary facilities for the maintenance of the bodily cleanliness which is the first of sanitary virtues to preserve neatness and order in the dormitories, and to prevent any portion of their cubic space from being occupied by dirty clothing Mr Sargant further claims that the saving of labour effected by the arrangement is a sufficient compensation for the cost of the first outlay

DIFFUSE ENCEPHALITIS DUE TO THE PNEUMOCOCCUS

IN recent years the widespread extent of the lesions which may be produced by the pneumococcus has been shown but in only a limited number of cases has infection of the brain been observed In the *Boston Medical and Surgical Journal* of Dec 15th, 1904 Dr W N Bullard and Dr F R Sims have reported the following case A man aged 50 years, was admitted to the Boston City Hospital under the care of Dr Shattuck The patient had been in good health until his present illness which had confined him to bed for a month He had a cough and expectorated thick white sputum, occasionally tinged with blood On admission he was under the influence of alcohol and was delirious Bronchitic râles were heard in the chest and there was dulness at the bases of the lungs There was a scar on the glans penis Three days later he was comatose and cyanotic and there was left hemiparesis The respiration was at times rapid and superficial and sometimes suggested Cheyne Stokes breathing The pupils were contracted The left limbs were flaccid , the right were rigid The morning temperature was 102° F the pulse was 72, and the respirations were 43 On the sixth day after admission the cyanosis was increasing and there was profuse perspiration The pupils were contracted and the left was slightly smaller than the right Death took place on this day At the necropsy yellowish white plugs could be expressed from the larger bronchioles and the bronchi contained purulent secretion The left pulmonary artery was occluded by a partially organised adherent clot The dura mater was thickened and adhered to the calvarium and to the pia mater along the longitudinal fissure The pia mater about the superficial veins of the sulci was thickened The brain was asymmetrically swollen The right parietal lobe was softer than the remainder of the brain The right centrum ovale and the subcortical projection system were œdematous and showed numerous punctiform hæmorrhages , the left centrum ovale showed slight œdema and a few hæmorrhages Microscopic examination showed pneumococci in the viscera and in the œdematous areas of the brain There were pneumococcic septicæmia, acute broncho pneumonia and diffuse encephalitis with hæmorrhages The lesions in the brain consisted of accumulations within and surrounding the adventitia of the vessels of large numbers of phagocyte granule cells of the type found in meningitis and cerebral softening and of small numbers of lymphoid and plasma cells with a few polynuclear leucocytes and eosinophiles solution and fatty changes of the myelin in the surrounding tissue proliferation of the neuroglia cells and œdematous changes in the cortical cells Acute non purulent encephalitis was first brought prominently forward by Strümpell in 1890 though he previously, in 1884 described the condition in children Cases were subsequently described by Schmidt, Furbringer, Konigsdorf, and others Many cases occurred after an attack of influenza or during an epidemic of the disease but in spite of several attempts the influenza bacillus could not be cultivated The best description of the disease has been given by Oppenheim It may come on suddenly or may be preceded by headache, vertigo nausea and vomiting, general weakness, apathy, and

six months old were investigated with the following results —

Babies who died from epidemic diarrhœa	Breast fed only	10 per cent	Out of 236 cases investigated
	Breast and bottle	10 "	
	Bottle only	80 "	

These figures may be supplemented by those of Dr E W Hope with respect to Liverpool, but it is important to note that such figures relate to children under three months of age —

Deaths from epidemic diarrhœa 0-3 months	Breast fed	20 deaths per 1000 infants
	Bottle fed	300 " " "

Dr Robertson's recommendations are chiefly directed to securing greater cleanliness in the food and surroundings of young infants, that is to say, attention to badly constructed and dirty houses and more personal cleanliness among the poorer classes Poverty, a factor which Dr Robertson evidently sees is perhaps the *main* factor in the problem, is such a delicate question that he refers to it only in relation to the enormous influence which drink possesses in promoting and accentuating its effects But, briefly summed up, all Dr Robertson's recommendations centre around the better education of the children and parents in the principles and practice of hygiene In the matter of milk supply he shows by the aid of a spot map that the milk of Birmingham is almost entirely derived within a radius of 50 miles of the city, and this being so there should, he thinks, be no delay in transit But the cowsheds in which the cows are milked are of the usual rural type and Dr Robertson advises the more [illegible] special Parliamentary powers [illegible] which enable its officers to repc [illegible] to the local authorities and, if they refuse to take action to make representations to the county council and the Local Government Board Finally Dr Robertson is evidently in favour of a municipal milk depôt on the lines of those of certain [illegible] making inquiries concerning [illegible] a day nursery for children

VITAL STATISTICS

HEALTH OF ENGLISH TOWNS

IN 76 of the largest English towns 9190 births and 5387 deaths were registered during the week ending Feb 4th The annual rate of mortality in these towns, which had been 17 5, 18 1, and 18 4 per 1000 in the three preceding weeks, declined again to 18 0 per 1000 last week In London the death rate was 17 5 per 1000 while it averaged 18 2 per 1000 in the 75 other large towns The lowest death rates in these towns were 9 0 in King's Norton, 11 6 in Bury 11 8 in Handsworth (Staffs), 12 0 in York, 12 1 in Walthamstow, 12 2 in Rotherham, 12 3 in Southampton, and 12 4 in Hornsey, while the highest rates were 23 6 in Wolverhampton and in Nottingham, 23 8 in Plymouth, 26 5 in Swansea, 28 1 in Norwich 28 8 in Stockton on Tees 31 3 in Middlesbrough 31 7 in Rhondda 31 1 in Hanley, and 33 2 in Merthyr Tydfil The 5387 deaths in these towns last week included 368 which were referred to the principal infectious diseases against 378, 358 and 376 in the three preceding weeks, of these 368 deaths, 114 resulted from whooping cough, 94 from measles 60 from diphtheria, 39 from scarlet fever 35 from diarrhœa 22 from "fever (principally enteric), and four from small pox In Brighton Southampton Northampton Walsall Stockport Huddersfield, and 12 other smaller towns no death from any of the principal in [illegible] hey caused the highest [illegible] Grimsby, Nottingham [illegible] Merthyr Tydfil The [illegible] measles occurred in [illegible] Merthyr Tydfil from scarlet fever in Hanley from diphtheria in Bournemouth, Middlesbrough and [illegible] in Willesden, Hastings [illegible] Barrow in Furness, from [illegible] and from diarrhœa in West Bromwich Of the four fatal cases of small pox registered in these towns one belonged to Leeds one to Hull, one to South Shields, and one to Newcastle upon-Tyne The number of small pox patients in the Metropolitan Asylums Hospitals, which had been 19, 18, and 15 at the end of the three preceding weeks, had further fallen to 13 at the end of last week, one new case was admitted during the week, against one, one and none in the three preceding weeks The number of scarlet fever patients remaining under treatment in these hospitals and in the London Fever Hospital on Saturday, Feb 4th was 2070, against 2192 2174, and 2096 on the [illegible] cases were admitted dur [illegible] 251 in the three precedir [illegible] ferred to pneumonia and diseases of the respiratory system, which had been 401 477, and 478 in the three preceding weeks declined again last week to 444, but were 94 above the number in the corresponding period of last year The causes of 69 or 1 3 per cent, of the deaths in the 76 towns were not certified either by a registered medical practitioner or by a coroner All the causes of death were duly certified in West Ham Portsmouth Bolton Cardiff, and in 40 other smaller towns the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Bootle, Warrington and Sunderland

HEALTH OF SCOTCH TOWNS

The annual rate of mortality in eight of the principal Scotch towns which had been 21 6, 20 1, and 20 3 per 1000 in the three preceding weeks, declined again to 19 9 per 1000 during the week ending Feb 4th, but was 1 9 per 1000 in excess of the mean rate during the same period in the 76 large English towns The rates in the eight Scotch towns ranged from 14 1 in Greenock and 15 8 in Paisley to 24 1 in Dundee and 32 8 in Perth The 668 deaths in these towns last week included 46 which were referred to whooping cough, 19 to diarrhœa nine to diphtheria six to measles, four to 'fever' (including two cases of typhus), and one to scarlet fever In all 85 deaths resulted from these principal infectious diseases last week against 85 72, and 79 in the three preceding weeks These 85 deaths were equal to an annual rate of 2 5 per 1000 which was 1 3 per 1000 above the mean rate last week from the same diseases in the 76 large English towns The fatal cases of whooping cough which had been 45, 33, and 44 in the three preceding weeks, further rose last week to 46 of which 31 were registered in Glasgow, four in Edinburgh, three in Perth, two in Aberdeen two in Paisley, and two in Greenock The deaths from diarrhœa, which had been 16, 17, and nine in the three preceding weeks further rose to 19 last week, and included 12 in Glasgow, three in Edinburgh and two in *Aberdeen* The fatal cases of diphtheria which had been five, three and nine in the three preceeding weeks, were again nine last week, and included six in Glasgow and two in Edinburgh The six deaths from measles corresponded with the number in the preceding week and included five in Glasgow The fatal cases of 'fever,' which had been three and six in the two preceding weeks, declined again last week to four, of which one case of typhus was registered in Dundee and one in Aberdeen The deaths referred to [illegible] 183 166 [illegible] ing period of last year The causes of 35, or more than 5 per cent, of the deaths registered in these eight towns last week were not certified

HEALTH OF DUBLIN

The death rate in Dublin, which had been 22 6 21 2 and 25 5 per 1000 in the three preceding weeks declined again to 24 2 per 1000 during the week ending Feb 4th During the past four weeks the death rate has averaged 23 4 per 1000, the rates during the same period being 17 2 in London and 19 6 in Edinburgh The 176 deaths of persons belonging to Dublin registered during the week under notice showed a decline of nine from the number in the preceding week and included nine which were referred to the principal infectious diseases against 21 10 and 18 in the three preceding weeks, of these five resulted from measles two from whooping cough, one from scarlet fever and one from *diphtheria but not any from small pox,* "fever' or diarrhœa These nine deaths were equal to an annual rate of 1 2 per 1000 the death rates last week from the principal infectious diseases being 1 1 *in London* and 1 7 in Edinburgh The fatal cases of measles which had been 12, five, and 13 in the three preceding weeks, declined again last week to five. The 176 deaths in Dublin last week included 32 of children under one year of age and 55 of persons aged 60 years and upwards; the deaths both of infants and of elderly persons were slightly in excess of the respective numbers recorded in the preceding week. Five inquest cases and four deaths from violence were registered; and 69, or nearly two-fifths, of the deaths occurred in public institutions. The causes of seven, or nearly 4 per cent., of the deaths registered in Dublin last week were not certified.

VITAL STATISTICS OF LONDON DURING 1904.

COMPLETE statistics relating to sickness and mortality during the year 1904 in each metropolitan borough and in the City of London will be found summarised in the accompanying table. The mortality figures relate to the deaths of persons actually belonging to the various boroughs, and are the result of a complete system of distribution of the deaths occurring in the public institutions of London among the boroughs in which the deceased persons had previously resided. With regard to the notified cases of infectious diseases in London during 1904, it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to 6·1 per 1000 of the population, estimated at 4,648,950 persons in the middle of last year. In the three preceding years the rates had been 8·9, 9·9, and 6·0 per 1000 respectively. Among the various metropolitan boroughs the rates last year ranged from 3·2 in Chelsea, 3·7 in Kensington, the City of Westminster, and Hampstead, 4·2 in Lewisham, and 4·5 in Lambeth, to 7·1 in Deptford, 7·2 in Bermondsey, 8·5 in Hackney, 9·3 in Poplar, 9·4 in Stepney, and 11·6 in Bethnal Green. The prevalence of small-pox was slightly greater than it had been in the preceding year, 491 cases being notified in 1904 against 416 in 1903. This disease was proportionally most prevalent in Stoke Newington, Finsbury, Bethnal Green, Stepney, Poplar, and Bermondsey. The number of small-pox patients admitted into the Metropolitan Asylums Hospitals was 512, against 1788, 8455, and 414 in the three preceding years; 17 cases remained under treatment at the end of the year, against 666, 14, and four at the end at the three preceding years. Scarlet fever was slightly more prevalent in 1904 than in the preceding year, the number of cases notified being 13,438, against 18,390, 18,258. and 12,531 in the three preceding years. Among the various metropolitan boroughs this disease showed the highest proportional prevalence in St. Pancras, Hackney, Bethnal Green, Stepney, Camberwell, Deptford, and Woolwich. During last year 11,629 scarlet fever patients were admitted into the Metropolitan Asylums Hospitals, against 14,959, 15,133, and 10,808 in the three preceding years; the number of cases remaining under treatment at the end of the year was 2349, against 3030, 2327, and 1606 at the end of the three preceding years. The prevalence of diphtheria during last year showed a slight decline; 7220 new cases were notified, against 12,154, 10,735, and 7738 in the three preceding years. The greatest proportional prevalence of this disease occurred in Hammersmith, Fulham, Hackney, Bethnal Green, Stepney, and Poplar. The Metropolitan Asylums Hospitals contained 800 diphtheria patients at the end of last year, against 1369, 927, and 734 at the end of the three preceding years; the number of admissions, which had been 9090, 7988, and 6158 in the three preceding years, further declined last year to 5783. A further considerable decrease in the prevalence of enteric fever took place during the year under notice, the number of notified cases, which had been 3195, 3412, and 2339 in the three preceding years, having fallen to 1896 last year. Among the various metropolitan boroughs this disease was proportionately most prevalent in St. Pancras, Hackney, Holborn, the City of London, Stepney, and Bermondsey. The number of enteric fever patients admitted into the Metropolitan Asylums Hospitals during 1904 was 1008, against 1480, 1806, and 1247 in the three preceding years; 159 cases remained under treatment at the end of December last, against 195, 210, and 246 at the end of the three preceding years. Erysipelas showed the highest proportional prevalence in St. Marylebone, Shoreditch, Bethnal Green, Stepney, Southwark, and Bermondsey. The 273 cases of puerperal fever notified during the year were 40 in excess of the number in the preceding year; 24 cases belonged to Islington, 23 to Hackney, 16 to Lambeth, 15 to Stepney, 15 to Poplar, 14 to Wandsworth, and 13 to Camberwell.

During the year under notice, 74,555 deaths of persons belonging to London were registered, equal to a rate of 16·1 per 1000, against 17·1, 17·2, and 15·2 per 1000 in the three preceding years; the average rate for the ten years 1894–1903 was 17·9 per 1000. Among the various metropolitan boroughs the lowest death-rates last year were 10·2 in Hampstead, 12·0 in Lewisham, 13·3 in Stoke Newington, 13·4 in Wandsworth, 13·5 in the City of Westminster, and 13·8 in Paddington; while the highest rates were 19·3 in Bethnal Green, 19·4 in Stepney, 20·0 in Bermondsey, 20·1 in Southwark, 20·4 in Shoreditch, and 21·3 in Finsbury. In the five groups of boroughs the rates were 14·6 in the west, 15·3 in the north, 15·5 in the south, 19·3 in the east, and 19·8 in the central. To the principal infectious diseases 9906 deaths were attributed during the year; of these, 25 resulted from small-pox, 2256 from measles, 365 from scarlet fever, 723 from diphtheria, 1495 from whooping-cough, 286 from enteric fever, six from ill-defined forms of continued fever, and 4750 from diarrhœa, but not one from typhus fever. These 9906 deaths were equal to an annual rate of 2·14 per 1000; the corresponding rates in the three preceding years were 2·22, 2·21, and 1·75 per 1000 and the decennial average was 2·47 per 1000. Among the various metropolitan boroughs the death-rates from these principal infectious diseases ranged from 0·60 in the City of London, 0·66 in Hampstead, 0·87 in the City of Westminster, 1·13 in Stoke Newington, 1·41 in Lewisham, and 1·45 in Kensington, to 2·57 in Finsbury, 2·84 in Stepney, 2·95 in Bethnal Green, 3·13 in Southwark, 3·20 in Shoreditch, 3·35 in Poplar, and 3·52 in Bermondsey. The fatal cases of small-pox numbered 25, against an average of 180 in the ten preceding years; of these 25 cases seven belonged to Bethnal Green, three each to Finsbury, Stepney, and Poplar, two each to Paddington, Holborn, and Shoreditch, and one each to Kensington, Islington, and Southwark. The 2256 deaths referred to measles were 333 fewer than the corrected average number; among the various metropolitan boroughs this disease was proportionally most fatal in Hammersmith, Holborn, Shoreditch, Bethnal Green, Southwark, and Bermondsey. The 365 fatal cases of scarlet fever were 292 below the average number in the ten preceding years; the greatest proportional mortality from this disease occurred in Finsbury, Bethnal Green, Poplar, Bermondsey, and Woolwich. The 723 deaths from diphtheria showed a decline of 1186 from the corrected average number: among the various metropolitan boroughs this disease was proportionally most fatal in Hackney, Bethnal Green, Stepney, Poplar, and Woolwich. The 1495 fatal cases of whooping-cough were 484 fewer than the average number in the ten preceding years; the highest death-rates from this disease were recorded in Shoreditch, Poplar, Southwark, Bermondsey, Greenwich, and Woolwich. The deaths referred to different forms of "fever," which had averaged 636 in the ten preceding years, had declined to 292 last year; among the various metropolitan boroughs "fever" was proportionally most fatal in Hackney, Finsbury, Stepney, Southwark, Bermondsey, and Greenwich. The 4750 fatal cases of diarrhœa were nearly 1200 in excess of the average; this disease showed the greatest proportional mortality in Fulham, Shoreditch, Stepney, Poplar, Southwark, and Bermondsey. In conclusion, it may be stated that the aggregate mortality in London last year from the principal infectious diseases was 13·7 per cent. below the average.

Infant mortality, measured by the proportion of deaths under one year of age to registered births, was equal to 144 per 1000 last year, against 148, 139, and 130 in the three preceding years. The rates of infant mortality in the various metropolitan boroughs ranged from 94 in St. Marylebone, 104 in the City of London, 109 in Holborn, 113 in Hampstead, 114 in Stoke Newington, 122 in Wandsworth, and 123 in Lewisham, to 154 in Poplar, 155 in Stepney, 156 in Chelsea, 157 in Bethnal Green, 172 in Bermondsey, 174 in Southwark, and 188 in Shoreditch.

UNIVERSITY OF DURHAM: FACULTY OF MEDICINE.—The Senate of the University of Durham has decided that German may be offered as an alternative subject for Greek in the preliminary examination for the degrees of doctor in medicine and master in surgery. This alteration will come into force in September, 1906.

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING THE YEAR 1904.

(*Specially compiled for* THE LANCET.)

CITIES AND BOROUGHS.	Estimated population in the middle of 1904.	NOTIFIED CASES OF INFECTIOUS DISEASE. Small pox.	Scarlet fever.	Diphtheria.*	Typhus fever.	Enteric fever.	Other continued fevers.	Puerperal fever.	Erysipelas.	Cholera.	Total.	Annual rate per 1000 persons living.	DEATHS FROM PRINCIPAL INFECTIOUS DISEASES. Small pox.	Measles.	Scarlet fever.	Diphtheria.*	Whooping-cough	Typhus fever.	Enteric fever.	Other continued fevers.	Diarrhœa	Total.	Annual rate per 1000 persons living.	Deaths from all causes.	Death rate per 1000 living.	Deaths of infants under one year to 1000 births.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

Inspector-General of Hospitals and Fleets Herbert Mackay Ellis, Director-General of the Medical Department of the Navy, has been appointed Honorary Physician to His Majesty in place of Inspector-General of Hospitals and Fleets Sir James John Louis Donnet, K.C.B., deceased (dated Jan. 13th, 1905).

The following appointments are notified:—Staff Surgeons: M. L. B. Rodd to the *President*, additional, for a three months' hospital course at the West London Hospital; J. C. G. Reed to the *Vulcan* on recommissioning. Surgeons: A. A. Forrester, lent for duty at New Hospital, Chatham. R. M. Richards to the *Vulcan* on recommissioning; F. R. Mann to the *Fire Queen*, for disposal; C. M. Woods to the *Sapphire II.* on commissioning; and D. H. Vickery to the *Wildfire* for disposal.

ROYAL ARMY MEDICAL CORPS.

Major H. M. Adamson is appointed to command the Station Hospital, Shahjehanpur, vice Lieutenant-Colonel G. F. Gubbin. Captain P. S. Lelean assumes medical charge of women and children, Marlborough Lines, Aldershot.

Colonel J. M. Beamish is placed on retired pay (dated Jan. 26th, 1905). Lieutenant-Colonel C. B. Hill is placed on temporary half-pay on account of ill-health (dated Jan. 29th, 1905). The undermentioned Lieutenants to be Captains:—W. J. S. Harvey (dated Jan. 14th, 1905) and B. A. Craig (dated Jan. 29th, 1905).

Captain E. Blake Knox is appointed secretary to Surgeon-General Sir Thomas Gallwey, K.C.M.G., C.B., A.M.S., Principal Medical Officer of His Majesty's Forces in India.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Lieutenant P. J. O'Sullivan, 1st City of London Royal Garrison Artillery (Volunteers), to be Surgeon-Lieutenant (dated Feb. 4th, 1905).

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): 1st Fifeshire: Surgeon-Captain H. W. Laing resigns his commission (dated Jan. 28th, 1905). 1st Essex: William Douglas Watson to be Surgeon-Lieutenant (dated Feb. 8th, 1905).

Rifle: 2nd Volunteer Battalion the Norfolk Regiment: Surgeon-Captain S. J. J. Kirby, from the 2nd Volunteer Battalion the Suffolk Regiment, to be Surgeon-Captain (dated Jan. 28th, 1905). 5th (The Hay Tor) Volunteer Battalion the Devonshire Regiment: Surgeon-Lieutenant-Colonel W. H. Webb is granted the honorary rank of Surgeon-Colonel (dated Feb. 8th, 1905). 1st (Brecknockshire) Volunteer Battalion the South Wales Borderers: Surgeon-Lieutenant-Colonel P. E. Hill (Brigade-Surgeon-Lieutenant-Colonel, Senior Medical Officer, South Wales Border Volunteer Infantry Brigade) is granted the honorary rank of Surgeon-Colonel (dated Feb. 8th, 1905). 1st Bucks: Supernumerary Surgeon-Lieutenant-Colonel W. H. Bull (Brigade-Surgeon-Lieutenant-Colonel, Senior Medical Officer, Home Counties Volunteer Infantry Brigade), is granted the honorary rank of Surgeon-Colonel (dated Feb. 8th, 1905). 1st Volunteer Battalion the Northamptonshire Regiment: George Herbert Lewis to be Surgeon-Lieutenant (dated Jan. 28th, 1905).

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

The Woolwich Companies: Major C. H. Hartt is granted the honorary rank of Lieutenant-Colonel (dated Jan. 28th, 1905); Captain (Honorary Captain in the Army) M. Taylor is granted the honorary rank of Major (dated Jan. 28th, 1905).

OUR RECRUITING ARRANGEMENTS.

As our readers are well aware, we have frequently in the past called attention to the very inadequate arrangements that are made for the accommodation of army recruits. We are glad, therefore, to notice that the *Army and Navy Gazette*, after also repeatedly urging the importance of this matter, again returns to the subject. Our service contemporary says:—

> Mr. Arnold-Forster has expressed himself anxious to do all in his power to render the army attractive. As a beginning he mi[illegible] call for reports on the situation and adaptability of recruiti[illegible] in large towns. If he is really desirous of [illegible] the joining the ranks he could take no step whi[illegible] be in producing this end than by arranging t[illegible] of all recruiting districts shall be so located that no self-respecting young man will shrink from presenting himself at them for the purpose of enlistment.

A measure of this kind would be a practical reform which would meet with the approval of everyone.

ROYAL ARMY MEDICAL CORPS EXAMINATION.

The undermentioned were successful at the recent competitive examination in London for commissions in the Royal Army Medical Corps. 68 candidates entered.

THE WAR IN THE FAR EAST.

The *Times* of Feb. 6th, in its first leading article, gave a most interesting *résumé* of the momentous events which have taken place since the negotiations between Japan and Russia were broken off on the evening of Feb. 5th, 1904. In the 12 months that have elapsed since then there have occurred those remarkable changes in the history of the world with which all are acquainted. What the end of this war will be no one can, of course, foretell with any certainty. But we have meanwhile been living witnesses of "history in the making" on a large scale and cannot avoid perceiving that the events of the past year have made an indelible stamp upon the record of the present time. What influence will this have on the trend of events in the history of the future? There are at the moment of writing some vague rumours of peace in which, however, no one apparently believes. Public attention at present continues to be attracted rather to the internal condition of Russia and the disturbed state of Poland than to what is going on in Manchuria. Much has nevertheless been taking place there of great military importance although not of any decisive nature. The cold is extreme and how the Russians continue to supply their enormous forces in the field with food, fuel, clothing, and the stores and munitions of war through the Trans-Siberian railway remains a puzzle to military officers. Still, to their great credit, be it said, it is done.

There is but little of any special medical interest to be recorded. The returns obtained from the chief surgeon with General Oku's army are, however, of considerable importance. According to these there have only been 40 deaths from disease in his entire command (strength not given) since its landing on May 6th last. The figures show that of the 24,642 cases treated up to Dec. 1st, 18,578 recovered, 40 died, and 5609 were sent to Japan. It is believed that these figures are unequalled in the history of warfare. There were only 193 cases of typhoid fever and 342 cases of dysentery but the number of cases of beri-beri was 5070. The other cases were not serious. Of the casualties sustained by the army from May 6th to Dec. 19th 16 per cent. of the wounded died, 19 per cent. recovered on the field, and 65 per cent. were sent to Japan. 85 per cent. of the wounds were caused by rifle [illegible] 8 per cent. by shells, and 7 per cent. by [illegible] thr[illegible] The largest percentage of re[illegible] the chest, while as regards other [illegible]ies was larger from wounds in the head and the abdomen than from injuries of other regions This is attributed to the small calibre of modern rifles, the percentages in the other Japanese armies being, it is believed, about the same Beri beri has been a very prevalent and probably fatal disease among the Japanese armies but we have no estimate as to the number of deaths which it has caused during the campaign The disease is the scourge of Oriental armies but the Japanese have of late years done much to mitigate its ravages especially in their navy Some very elaborate articles have appeared comparing the losses of the belligerent armies with one another during the year's war but at best the numerical results can only be approximate and untrustworthy at the present time

Surgeon General G J H Evatt, C B, retired list, A M S, has been finally adopted as Liberal candidate for the Southern Division of Hampshire at the general election

THE CANCER PROBLEM AND CANCER RESEARCH

To the Editors of THE LANCET

SIRS,—No doubt you a
Registrar General every y
malignant disease in the B
fact was sufficient reason
of, any feeble attempts of mine to solve the problem of cancer If my findings be wrong that has still to be demonstrated, and unfortunately you and your medical colleagues in Great Britain have at present nothing else to offer those 28 000 annual victims! This reflection might serve to give you pause You decided to publish my paper and for that courtesy I am grateful In your leader some of my embryological conclusions are referred to in very scathing terms, but that cannot in the least impugn their truth In the near future you may see cause to regret the terms of that leader and you may come
contained more truth than your
suspected If my conclusions b
any vital embryological probler
cancer problem has almost certainly been lifted into a new region, that of physiological chemistry I am not anxious to carry on a futile controversy with an editor in his own journal, even with editors so courteous as those of THE LANCET But I would ask that courtesy to note or correct a few things in your leader Before all else the following statement is open to very serious misconstruction "The writer states that it is based on work carried out with the support of the ample funds for research at the disposal of the Carnegie trustees and the Moray Research Fund of the University of Edinburgh

The funds for research are not ample If you still think them to be so I would ask you to take the opinion of the secretary of the Carnegie Trust The reference to these two funds was necessary because I happen to hold grants from them for certain research purposes and the Carnegie Trust lays down as a condition that in all published work the fact of a grant having been made shall be stated *The footnote refers to my work on various problems during the past 16 years* From 1890 to 1898 these researches were carried out from my own slender private means and without grants from any source Every bit of my published work has left me poorer than when the research was commenced The work of the past two years upon tumours has not cost the Moray Research Fund a single penny and the total charge for tumour researches on the two grants from the Carnegie Trust amounts at the moment to £26 8*s* 5*d* Of this sum since last October £16 has been paid in wages to a youth who at the cost of much of my time and patience, has been made into a useful technical assistant &c He has, in fact been trained, and is still under instruction to be a skilled laboratory assistant for the University of Edinburgh So that the real net cost of my tumour work has been £10 8*s* 5*d*, or at the rate of £5 4*s* 2½*d* per annum The amount is rather excessive owing to a loss of 50*s*, the price of a certain dog which was secured by me for the Liverpool Cancer Research, but which was sacrificed at the altar of science accidentally by an Edinburgh surgeon Certain other published balance sheets of cancer research occur to one but comparisons are odious

There is no call for a new defence of my embryological conclusions in your pages Had the writer of your leader appended his name there would have been no occasion for any further reply from me The theory of heredity based in "unconscious memory" is not mine but that of a very distinguished
of Prague Had the quotations
been made from your pages of
from those of your issue of
June 21st 1902 a revised modern version of my conclusions would have resulted As to the mimicry of the tumours it suffices for me that Sir James Paget and Fleischmann recognised it long ago, but it has never been held by me that a cancer or sarcoma "takes on the histological character of the tissue in which it is growing" It only tries to do so, and often enough it resembles no normal tissue whatever If a cancer be somatic in origin, how does this happen? Schmorl's finds of bits of the trophoblast in the lungs in pregnancy no more refute the existence of the unlimited powers of growth than would the failure of an attempt to grow rose cuttings in a cinder heap prove that the rose had only limited powers of growth His finds were made *in pregnancy and with a normal embryo or fœtus present* The whole histories of hydatid mole and of chorio epithelioma amply illustrate these powers, which can only on occasion be exercised in the absence of a normal embryo As to the erosion of a bone by an aneurysm, I have heard that simile several times before Presumably it is not suggested that the wall of the aneurysm or the blood does the erosion and possibly some enzyme of leucocytes, similar to, though perhaps not the same as that found in malignant growths, may have some concern in the matter

You or your leader writer, wish to eliminate the germ cell theory of cancer Should you succeed there would always be a problem of cancer Is any parasitic theory better? On p 322 of your current issue you express the wish that my friend Dr W Ford Robertson and Mr H Wade will succeed in establishing their thesis" I, too, would gladly share this hope but unfortunately it is impossible for these supposed cancer parasites appear to be due to the following (1) chromatolysis, (2) "tetrad" formation, (3) division of centrosomes, (4) degeneration of centrosomes, and (5) the so called "Nebenkern" What the student nowadays is expected to profess about enzymes is no concern of mine, but before allowing my paper to appear in print apart from the ordinary text books a close study was made of the following the latest editions of the two standard works of Verworn and Hoppe Seyler, the literature on enzymes cited therein, some results recorded by botanists and all the work of recent years published in the *Journal of Physiology* and in the *Boston Journal of Medical Research*, &c My chief authorities were given, which is, it may respectfully be submitted, more than can be said for many of the statements contained in your leader Regarding the point that "carcinoma is common to all vertebrates and the relation between cancer and uterine gestation suggested by me in 1902 it is quite true that cancer is common to vertebrates though it is anything but common in the lower vertebrates The investigators of the Imperial Cancer Research Fund gôt together ten cases from various parts of the world I have an eleventh but it may be doubted whether two dozen have as yet been recorded in the literature In the British Isles alone in 1902 27,872 people zoologically members of the class mammalia, died from malignant disease In view of these facts is it quite certain that uterine gestation has had nothing to do with its comparative frequency in man for example?

A recent writer in your pages remarked that the way of the transgressor was hard I have long realised how very hard and thorny it was but it is comforting to think that your leader was written in the twentieth century and not in the fifteenth Otherwise its effects would assuredly have been exceedingly painful for a certain person who has really very little enthusiasm for scientific research But with all deference the points are not whether my embryological results be "very hypothetical," notwithstanding all that some very distinguished men may think of them not whether the £10 8*s* 5*d* of Carnegie research money might have been devoted more profitably to some big cancer research, but whether the existence of an antithesis of enzymes be true and whether or not this be at the basis of all the havoc wrought by cancer. Should this be correct, what scientific value, if any, would attach to the strictures in your leading article? Were the researches of Petry and of Hartog (which I meant to do myself) "wild speculation"? If a malignant tumour possess an enzyme totally different from that widely present in traces in normal tissues, is not that a fact of supreme significance and import? I ask your readers to judge my work for themselves. Its chief conclusions have been advanced in Liverpool before an audience including leading surgeons, physicians, and pathologists, and again more recently in the presence of a certain distinguished physiologist. On these occasions they were listened to with the deepest interest and they evoked no adverse and depreciatory criticism whatever, even on the Edinburgh research funds. Lastly, let it not be forgotten that at times my findings and conclusions have an awkward habit of turning out to be true.

I am, Sirs, yours faithfully,

Feb. 5th, 1905. J. BEARD.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Jan. 14th, p. 120, under the heading "Local Irritation and Cancer," I suggested as an additional or alternative theory to cholesterine that glycogen in the same way leading to cell proliferation or alteration of type of division "may be due either to undue local deposition in the tissues or dependent on some nutritional disturbance in the liver or pancreas." Moreover, it had seemed to me, though I had not elsewhere seen it noted, that a similarity existed between this excess of glycogen in malignant growths and the excess of glycogen in fœtal tissues which obtains from a very early period up to the fifth month: when histological differentiation has largely advanced it begins to be deposited in the usual place, the liver, and its use to the economy becomes that to which it is put in the ordinary life of the animal (M. Foster).

In view of my belief, therefore, that in malignant disease the tissues have in some sense reverted to glycogenic tissue, either from over-production or non-conversion of glycogen, locally or generally, it may be of interest to point out that on Dec. 8th, 1904, I applied to Messrs. Parke, Davis, and Co. more especially to ascertain if taka-diastase had any amylolytic action on glycogen, suggesting at the same time pancreatic ferment. They replied that taka-diastase had little or no action but that the glycerine extract of pancreas had. Meanwhile as a result of experiments made by Mr. F. W. Gamble, pharmaceutical chemist, with various ferments, trypsin was found immediately and most effectually to break up glycogen. It is of interest, therefore, to me to find that Dr. J. Beard in his paper on the Cancer Problem[1] independently corroborates the view expressed in the above extract from my letter that it is the pancreas which is at fault. Though his explanation of the use of trypsin in fœtal life and presumably in malignant disease is different from mine it may interest him to learn that already on Jan. 19th, 1905, I had commenced to make trial of hypodermic injections of trypsin locally, together with the internal administration and outward application of pancreatic solution in a case of advanced recurrent cancer of the breast.

I am, Sirs, yours faithfully,
JOHN A. SHAW-MACKENZIE, M.D. Lond.

London, Feb. 6th, 1905.

THE PUBLIC HEALTH LABORATORY OF MANCHESTER.

To the Editors of THE LANCET.

SIRS,—Will you kindly allow me to rectify an error which has crept in in the account which you gave in your issue of Feb. 4th of the opening of the Public Health Laboratory in Manchester? Your informant states that there is a staff of 13 assistants, five students, one secretary, &c., in the laboratory. This statement is obviously the result of some confusion; there are only three medical assistants (Dr. Sidebotham, Dr. Carver, and Dr. Sellers) engaged in reporting to sanitary authorities, in addition to which Dr. Sidebotham is also lecturer in practical bacteriology and Dr. Sellers assistant lecturer in comparative pathology. Dr. G. Fowler has recently joined the staff as senior chemical assistant and Dr. Ramsden, who is University Fellow in Sanitary Chemistry, acts occasionally as junior assistant. No student or unqualified assistant takes part in public health investigations. There is also a technical assistant (Mr. Simons). The staff, including the secretary and myself, consists, therefore, of eight persons; only six, including myself, are qualified to undertake investigations for sanitary authorities. Several other gentlemen take part in the teaching of public health or other advanced students but they are not assistants in the department. Although the matter is not one of much importance I do not think it desirable to allow what might reasonably be considered a great exaggeration to come under my notice without attempting to rectify it.

I am, Sirs, y[illegible]

Feb. 7th, 1905.

THE PROGNOSIS OF ADOLESCENT INSANITY.

To the Editors of THE LANCET.

SIRS,—In an annotation in THE LANCET of Feb. 4th, p. 312, under the heading of "The Premature Dementia of Adolescents," you quote the opinion of Dr. Sérieux of Paris as to the curability of the "hebephrenic" and "katatonic" forms of "adolescent insanity" being only 1 in 10. In my opinion—and this has been formed on a careful study of the disease from statistical and clinical facts—the statement is calculated to produce a very unduly pessimistic and painful general effect on your professional readers who have to treat such cases and on readers who have relatives suffering from "adolescent insanity." The facts, I maintain, do not warrant such an unfavourable view. In 1873 I segregated and described a large group of mental cases with similar symptoms and called it "adolescent insanity." I subsequently gave an extensive series of clinical and statistical facts in support of my conclusion. The name and the description have been almost universally accepted by subsequent observers and authors, who, by the way, have seldom given me any credit for the induction. More recently German and American authors have adopted the term "dementia precox" to describe a sub-group comprised within adolescent insanity. Unfortunately no two of those authors mean the same thing by "dementia precox." Kraepelin has recently still further subdivided "dementia precox" into the divisions of "hebephrenic," "katatonic," and "paranoid." If any of your readers can form definite clinical pictures of those divisions from Kraepelin's descriptions and can then with confidence assort his patients under those groups I confess it is more than I have been able to do. I have always most strenuously contended that the term "dementia" should be reserved for incurable varieties of mental enfeeblement. This would save confusion, help to clarify our nomenclature, and, above all, would enable the general practising member of our profession to know better where they stand in using the word "dementia." I have no objection to the terms "hebephrenia" or "katatonia." I have much doubt about "paranoia," that fascinating and ever-changing rubbish heap of delusion, obsession, hallucination, and over self-appreciation into which some authors cast 50 per cent. of the insanities, and others—Kraepelin lately—restrict to about 5 per cent. of all the cases. But to attach those terms to forms of "dementia" seems to me an instance of medical classification gone to the verge of absurdity and confusion.

As to the curability of adolescent insanity, I took 1796 consecutive cases of insanity and found that 320 of these were in the developmental ages between 14 and 25 years inclusive. Of those 320 I had to deduct 90 as belonging to groups such as the epileptic and other forms. I found that the last five years, from 21 to 25, produced most of the 230 remaining cases, or about 70 per cent. of them. That is the time when the higher brain centres attain their full and final development. Especially do the highest emotional, volitional, and moral faculties then blossom and seed. To provide the infinitely delicate brain vehicle for such fruit of mental evolution must try to the utmost the potentialities of the developmental nervous process. It is then evidently that hereditary mental defects chiefly show themselves and cause psychical breakdowns, just as in the earlier years the lesser developmental neuroses, such as chorea, epilepsy, hysteria, somnambulism, asthma, and megrim, are most apt to appear. A careful study and summarising of the symptoms in the 230 cases showed that maniacal excitement, periodicity, acuteness, and strong sexual tincture were the dominant symptoms present while a mental or neurotic heredity was universally present. This is, in fact, by far the most hereditary of all the forms of insanity. Instead of mental incurability I found, however, that one characteristic of the disease was a recovery rate of 51 per cent, a higher rate than that of the insanities taken as a whole. No doubt there is a special liability to relapses in the future lives of these patients more than is the case in mental disease generally, but I can point to hundreds of men and women who have passed through attacks of adolescent insanity, have done their work in life well, and have had no relapses. The really sad part of the disease is that 30 per cent do not recover and do not die, but pass into that most typical of all the dementias the "secondary" or "sequential" form, who live on for years, waterlog our asylum wards, are burdens on our ratepayers and are the despair of the asylum physician—not to speak of his discredit in the public estimation. The higher mind has died in those dements while their bodies live, eat and need housing, clothing and supervision at a cost to the working citizen of from £25 to £40 a year each. The typical asylum dement has commonly begun as an adolescent maniac.

---

[1] THE LANCET, Feb. 4th, 1905, p. 281.

The latest work in our department of medicine strikes a note of greater hope for the adolescent insane. The application of exact bacteriological, toxæmic, and hæmatological methods in the study of such cases by Dr Lewis C Bruce seems to point to a far surer basis for our future classification of mental diseases than groups of symptoms or physiological crises of life. He seems to have isolated a "hebephrenia" and "katatonia" by careful study of blood conditions which point to toxins as its cause and to antitoxins as its remedy in the very early stages, those being detectable before the actual mental attacks. The man who will teach us how to prevent the occurrence of secondary dementia following on adolescent insanity will indeed lay humanity under a deep debt of obligation.—I am, Sirs, yours faithfully,

URANIUM SALTS IN CANCER

To the Editors of THE LANCET

SIRS,—In THE LANCET of Feb 14th 1903, p 476 and of April 18th, 1903 p 1126 you kindly gave me space to suggest the possible use of uranium salts in cancer. The following brief account of a case to some extent bears out that hope which I then expressed. The patient now aged 68 years had her right breast removed for cancer in July 1902, at the Royal Infirmary Liverpool. Secondary nodules began to show in December, 1903. Further surgery was deemed of no use and the patient was put on large doses of cinnamon. The case first came under my care in May 1904. Locally there were countless nodules in the skin varying in size from a pea to a marble mostly in the axillary region but extending forwards to the sternum and backwards to the spine on the right side of the chest.

Generally there

of the heart T

After eight mont

condition is as follows. Generally the health of the patient has much improved, the murmurs over the cardiac area have gone, she eats and sleeps well and for some months she has been able to do regular work as a seamstress. Locally dozens of the nodules have subsided and have become level with the skin and though at intervals a fresh nodule does come the total area involved is much less than before treatment began.

It might be urged that this is a case where the growth

ar but there was no evidence

d and if the patient omits it

so well. The first change in

d becomes tender and then

gradually dies down. The dose of salicylate of uranium for the first few days was five grains, then for six months 15 grains, and for the last two months 20 grains daily. The patient could no doubt, take bigger doses but there would be little gained, since the complaint seems to be under fair control. Salicylate of uranium was made at my suggestion by Messrs Burroughs Wellcome and Co. This firm now make five grain tabloids and the co[illegible]er 100 is about 5s. Finally, one may add that salicylate seems to be better tolerated than either nitrate or acetate of uranium.

I am, Sirs yours faithfully,

ARTHUR C WILSON

Formby, Feb 5th 1905

THE RECENT DISCUSSION ON CHLOROFORM ANÆSTHESIA

To the Editors of THE LANCET

SIRS,—The recent discussion on chloroform anæsthesia at the Royal Medical and Chirurgical Society is of great interest in more ways than one. It is for example significant that those having the greatest experience in the administration of the drug consider that danger lies in respiratory failure, but it is on the question of dosage that I desire the privilege of writing a few words. From the printed report it would certainly seem that contrary to what might have been expected in a discussion held at a society which was not composed of specialists the view taken of this aspect might have been a wider one. Dosage is after all only a means and usually a rough means to an end. When a drug is administered (for other than a purely local effect) a remote result is desired and in order that this may ensue the drug has to be absorbed into the blood circulation and then to reach the tissues through the lymph circulation. If such a drug is given as is usually the case by the mouth it may or may not be partly or wholly absorbed into the circulations. The result is quite indefinite and the physician is entirely in the dark as to the amount which still lies in the alimentary canal, that which is circulating, that which is fixed in the tissues and that which has already been excreted into the alveoli or ducts of one of the eliminating organs. Even could the amount of the drug which is fixed in the tissues be determined there is still the complicating uncertainty of idiosyncrasy which may or may not be dependent on such physiologico chemical union and in spite of what Sir Victor Horsley has said there can be no doubt that chloroform is in this respect no exception to all other

physician

drug, this

"dose,"

istration

entirely by the effects hitherto produced and no accuracy of dosage will prevent poisoning if the dose be too large or the subject unduly susceptible. Accuracy of dosage does not in any way absolve the physician from a close observation of the effects which his drug is producing. To these somewhat obvious general principles chloroform is no exception although there are differences in detail due to the unusual physical character of the drug and to the unusual channel of absorption and elimination. When the vapour of chloroform is inhaled it reaches the bronchioles carried by the tidal air, and with a fixed percentage of chloroform vapour the amount of chloroform which reaches the bronchioles will vary with the depth of inspiration. From there it diffuses into the infundibula and alveoli and some of it is absorbed, the amount which reaches and that which passes through the alveolar membrane into the blood varying with the amount present in the bronchioles—that is with the depth of inspiration. Any machine then, which delivers a fixed percentage may be passing to the patient a very variable amount of chloroform, as has been pointed out by Dr J F W Silk. It affords no basis for accurate dosage and the amount of chloroform which it offers for absorption into the blood varies from moment to moment. This element of uncertainty too, is further increased by the fact that when the partial pressures in blood and alveolar air are favourable chloroform is excreted by, instead of being absorbed by, the air passage, a fact made use of in the practice of artificial respiration for chloroform poisoning. Elimination is far more rapid than is the case with most drugs. It is evident, then that if there is a large element of uncertainty as to the amount of a drug given in the usual way by the mouth which is at any moment circulating in the body fluids or fixed in the tissues there is a far greater uncertainty as to the amount of chloroform present in these situations, and if it be essential that the physician should be guided entirely by

by the mouth

that he must

administering

chloroform by the air passages. By far the greater part of the chloroform which evaporates from any inhaler, whether a percentage one or not, is no more in the patient, within his respiratory endothelium that is, than if it were still in its bottle on the dispensary shelf, and if the use of an inhaler gives to the anæsthetist a false sense of security and tempts him to any relaxation of vigilance, a real danger among the less experienced, it will do an immense amount of harm. Passing in review all the uncertainties which must surround the administration of chloroform through a percentage inhaler, one is prepared for the statement made during the discussion that these instruments give no immunity from an overdose, but that such has actually occurred, and that in the hands of an experienced anæsthetist, artificial respiration having to be resorted to in order to save the patient's life. These regulators, then, are not safe. The use of one does not, any more than does the use of a hypodermic syringe in the case of morphia, introduce the element of safety into the administration of chloroform, and the administrator in determining whether or no more of the drug is required has to be guided by the effect produced as entirely as is the case when he administers any other drug by any other route. It has been shown that these regulators do not introduce into chloroform anæsthesia the element of safety. It is evident that it is as easy to kill a man with one of them as it is without. This being so, their sole possible advantage is lost, while by their use there is introduced the enormous disadvantage that the attention of the anæsthetist is divided between the patient and the apparatus. There is a real danger here that the general use of such apparatus will increase the death-rate, for there can be no question that chloroform cannot be given safely unless the whole attention of the administrator is concentrated on the patient and in particular upon the respiration. It is possible that it is not altogether easy for some specialists in anæsthetics to realise this, for by long practice the noting of the various points which make up normal anæsthesia becomes sub-conscious and automatic, while at the same time any variation from the normal thrusts itself immediately upon their attention. But in the case of the less experienced—those, that is, in whose practice deaths from chloroform poisoning are most likely to occur unless the whole attention is concentrated on the patient—the first signs of danger may easily be missed and the patient be beyond recovery before it is realised that he is in danger. It is admissible to repeat that chloroform cannot be given with safety, at least by any but the most experienced, unless the whole conscious attention of the administrator is concentrated on the patient and especially on his respiration, and the use of a machine, which divides his attention introduces at once into the administration the danger of fatal poisoning.

FRACTURED HUMERUS IN AN ARM AFFECTED BY INFANTILE PARALYSIS.

To the Editors of THE LANCET.

rs,—I have met with a case recently which is quite new experience nor can I find any local *confrère* who has met with a similar case—viz., a young lady, aged 21 who has one arm quite paralysed—all the muscles have sted since early childhood—recently fell and fractured rus of the paralysed arm. What are the chances of ous union? The fractured arm is thoroughly fixed narrow Cline's splints and there is no movement of hich has also a retaining bandage over the injured the thorax, permitting the sound arm, of . She is taking hypophosphites and generous meal bread, &c. Her constitution seems lly. Is there any work treating of such a ' opinion as to the probable ultimate result reciated.

I am, Sirs, yours faithfully,
RAPIER.

paralysis of the muscles of a limb does arm and speedy union of a case mentioned by our correspondent, only paralysis of the muscles of the limb but also more or less atrophy of the bones, so that there may be little compact bone in the shaft of the humerus. In such a case some delay in union may occur but ultimately the fragments should unite firmly. In the treatment of such a fracture it is well to remember that the tissues of the paralysed limb are not of a very high degree of vitality and therefore especial care should be taken to prevent pressure sores from the splints.—ED. L.

NITROUS OXIDE GAS, CHLOROFORM, AND AIR INTIMATELY MIXED.

To the Editors of THE LANCET.

SIRS,—Since you kindly inserted a short communication[1] from me on the merits of nitrous oxide gas, chloroform, and air intimately mixed either for short operations or as an introduction to prolonged insensibility by chloroform, I have had so many letters from different and far-away correspondents asking for a description of the apparatus that I have shown my own adaptation of the ordinary gas apparatus to Messrs. Down of St. Thomas's-street, who are now able to supply the necessary parts. My former communication was rather to draw attention to the principle as I thought almost anyone could adapt the Woulfe's bottle. I may add two things: I commence to use the Woulfe's bottle as soon as I turn on the gas, and I find some 50 per cent. of the patients give a slight moan after a few seconds' inhalation though as yet on inquiry after recovery I have not found one patient cognisant of it.

I am, Sirs, yours faithfully,
TOM BIRD,
Feb. 2nd, 1905. Consulting Anæsthetist, Guy's Hospital.

THE SERUM THERAPEUTICS OF CASES OF SNAKE-BITE.

To the Editors of THE LANCET.

SIRS,—Captain G. Lamb, I.M.S., in his interesting paper in THE LANCET of Nov. 5th, 1904, p. 1273, on the above subject refers once more to the experiments (published in my lecture in your columns on Feb. 6th, 1904, p. 349) in which I obtained complete recoveries of animals from eight and more lethal doses of the venoms of the cobra, king cobra, enhydrina, and bungarus cœruleus respectively previously mixed with relatively large doses of Calmette's antivenin and he repeats his criticisms of these results on the ground that as Calmette's serum is made from a mixture of venoms it is by no means suitable for the settlement of the specificity of the venoms. As, however, I have recently been informed by M. Calmette that the antivenin he supplied me for the experiments referred to was made purely by the use of cobra venom Captain Lamb's criticism falls to the ground, while he has himself pointed out that those who have failed to neutralise any of these venoms have used smaller doses of antivenin in proportion to the strength of the venoms tested than I did, so that their results agree with mine, for with the smaller doses of serum used by me the animals also died.

My excuse for returning to the subject is that my results have a practical as well as a theoretical value, for although by itself the strongest antivenins have to be used in practically impossible doses, even against cobra venom, if a full dose of the poison has been received, although it may save life if only a slightly supra-minimal lethal dose is injected (as in a case reported in the December number of the *Indian Medical Gazette*), yet if most of the venom is destroyed locally by the use of permanganate of potash, as recently re-advocated by Sir Lauder Brunton, Sir Joseph Fayrer, and myself (five successful cases of which treatment will shortly be published in India), then even a comparatively small amount of antivenin may suffice to reduce the amount of any of the colubrine venoms mentioned, which may have already entered the circulation before the local treatment is completed, to below a fatal dose and so save life. The cobra antivenin should therefore be used, if available, in every case which may possibly be due to a colubrine snake but it should be always injected intra[illegible]nously, as both

MULTIPLE GESTATION

To the Editors of THE LANCET

SIRS,—In your notice of Dr Pinard s work on the phenomenon of multiple gestation you cite many remarkable cases of extreme fertility amongst women, and draw attention to the probability of this being an inherited character In support of this view the case of three sisters[1] in America who had between them 111 children deserves notice The eldest, Dr Mary Austin, who was well known for her work during the War of Independence, gave birth to triplets six times and to twins 13 times, making 44 in all The second sister had 41 children and the third 26 A point of interest in this case is that it is hardly in accord with the supposition that extreme fecundity may be due to the influence of the father, otherwise the long arm of coincidence would have to be unduly stretched Those of your readers who are interested in this question will find an able discussion of this and similar phenomena in the monograph by Dr M von Lenhossek, "Das Problem der geschlechts bestimmenden Ursachen

I am, Sirs, yours faithfully,

Windsor, Feb. 2nd 1905 M DAVENPORT HILL

INDIAN UNIVERSITY DEGREES AND THE ROYAL COLLEGE OF SURGEONS OF ENGLAND

To the Editors of THE LANCET

SIRS,—In relation to the degree of the University of Bombay I think it may be interesting to some to know that the F R C S and M R C S and L R C S are recognised in the Dental Act as degrees "*Licentiate*" in the Spanish universities is a very old degree and in our old universities Oxford and Cambridge "Licentiate" was a grade higher than M B I am, Sirs, yours faithfully,

J G PARSONS, F R C S Eng

Cotham Bristol, Feb 4th 1905

*** In Table G to be found in the Medical Register under the heading "Qualifications Now or Formerly Obtainable," "Licentiate in Medicine' is mentioned as a supplementary qualification to be obtained from the Universities of Oxford, Cambridge, and Durham As we were unacquainted with this "degree' we communicated with the Registrar of the University of Oxford who informs us that he had never heard of the degree "Licentiate in Medicine In mediæval times the "Bachelor of Medicine" was conferred at the same time as the "Inceptio ad lecturam' and the "M D" with the "Inceptio ad licentiam" This latter, we presume, is what Mr Parsons is referring to in his letter In 1854 we learn from 'The British Medical Directory" that the University of Cambridge conferred a licence *ad practicandum in Medicina* which was granted to candidates being previously Bachelors of Physic who could produce certificates of having attended hospital practice for three years and of having attended lectures in medicine, surgery midwifery, and the collateral subjects Nothing is said however, in the same directory about a similar degree at the University of Oxford —ED L

THE HIGH DEATH-RATE OF THE COLOURED PEOPLE IN THE UNITED STATES OF AMERICA

(FROM OUR SPECIAL SANITARY COMMISSIONER)

IN America the difficulty of housing the poor is complicated with the negro problem The latter is a most formidable problem which by some is thought to threaten the very existence of the country The negroes multiply so rapidly that at least in some parts of the United States they threaten to overwhelm the white population But to deal with this matter needs special and close study and journeys further south than could be attempted in the limited time at my disposal It was at Washington and at St Louis that I came in nearest touch with the negro question and then mainly as an integral part of the housing problem The population of the District of Columbia, including the capital of Washington, is set down at 295,198 and out of this total 90,353 are negroes Now the average annual death rate for the years from 1894 to 1903 was 20 91 per 1000 Few, however look at the death rate in this light nor are the official figures given in this simple manner The average total certainly is set forth but it is always accompanied with other tables giving the death rate for the white and the coloured races separately Thus for the ten years in question the average annual death rate for the white races only amounted to 17 01 per 1000 On the other hand, the death rate for the coloured people was no less than 29 44 per 1000 A similar difference between the white and the coloured population is recorded in many places As already mentioned, the death rate of the coloured population at St Louis was 30 86 per 1000, while that of the white population was only 16 83 per 1000[1] The startling discrepancy between these figures has led to a widespread impression *that it was a question of race* But a closer examination indicates that the causes are poverty and bad sanitation rather than colour Indeed, there are some reasons why the negroes should live longer than the white men They are in any case less addicted to drink and they are less violent and not so likely to die from some accident Thus for instance, taking the deaths in the District of Columbia for the year 1903, it will be found that 19 deaths of the white and only four deaths of the coloured population are registered as due to alcoholism, giving a death rate per 1000 of 0 092 whites and 0 044 coloured or a ratio of 1 to 0 48 Again in regard to cirrhosis of the liver the death rate among the white population was 0 166 and among the coloured 0 089 per 1000, or a ratio of 1 to 0 53 For accidents the death rate is 0 679 among the whites and 0 597 among the coloured and for suicides the difference is 0 249 to 0 089, or a ratio of 1 to 0 36 to the advantage of the coloured people These figures show that the latter are more sober and less violent than the white men On the other hand the death rate from hereditary syphilis was only 0 015 per 1000 among the white and amounted to 0 100 among the coloured people Yet this may be due not so much to greater immorality but rather to ignorance and poverty which prevented the parents obtaining proper treatment in the early stages of the disease It is in respect to the more general causes of death that the coloured people especially suffer Thus the death rate per 1000 in 1903 was for diarrhœa and enteritis of children under two years, 0 556 among the whites and 1 859 among the coloured, for pneumonia at all ages 0 917 and 2 690 respectively, and for tuberculosis of the lungs 1 733 and 4 660 respectively The report of the health officer of the District of Columbia dealing with the figures for the year 1902 summarises the situation as follows —

> The excessive mortality of the coloured race begins with earliest infancy the ratio between the death rates for white and for coloured from premature births is as 1 to 2 26 The corresponding ratio from congenital debility is as 1 to 2 51 from malnutrition and marasmus as 1 to 2 24 and from rickets as 1 to 4 9 Child bearing is fraught too with peculiar dangers to coloured women The ratio between the death rates for white and for coloured from puerperal eclampsia is as

---

[1] See 'Sanitation at St Louis in THE LANCET of Dec. 17th, 1904, p 1753

1 to 3·13, from puerperal peritonitis as 1 to 1·46, and from puerperal septicæmia as 1 to 4·20. Disorders of the bowels among white children under two years of age caused a death-rate which compared with the corresponding death-rate among coloured children as 1 to 3·40. The relative incidence of fatal cases of convulsions of children on the white and coloured races is as 1 to 4·64. The relative incidence of hereditary syphilis is as 1 to 3·14.

These statistics undoubtedly indicate a great difference but similar contrasts could be found in other towns where there is no racial difference among the inhabitants. I discussed the matter with Dr. J. W. Cabaniss, who is himself a coloured general practitioner, and he maintained that in those tenement houses in the South of Washington which are overcrowded with poor people belonging to the white races the death-rate is as high as that of the coloured population. In Washington from 60 to 70 per cent. of the coloured people are unskilled and underpaid labourers, whereas among the white people not more than 12 per cent. are poor and badly paid. One of the causes of the high death-rate of the coloured population is that they are not allowed to join the white men's trade unions. Therefore coloured men have little or no opportunity of becoming skilled workers. Then, whether skilled or not, being excluded from the trade organisations they often do work equal to the white man's work but for less pay. The strong prejudice felt against coloured people is utilised as an excuse for paying less even when the best work is done. The government itself has a share in this injustice, for when a coloured man works for the authorities he is not as well paid as the white man though he performs the same task. Thus those coloured people who by their ability and industry are capable of raising the standard of living cannot do so to the same extent as the white men because they are not allowed to receive equal pay even when the work they do is equally good.

The coloured man, therefore, and whatever may be the nature of the work on which he is engaged, earns much less than the white man and yet his family will number nine or ten children while the white man will only have three or four. In such circumstances poverty, overcrowding, and a high death-rate are but the natural consequences. Inquiring what the poorer coloured folks ate I was told that at Washington they often had a little bacon for breakfast which they were able to buy for from 6*d.* to 9*d.* a pound or fish at 7*d.* a pound. Then many poor people waited to a late hour to buy remnants from the butchers just as the latter were about to close their shops. These pieces of meat had often been on ice for several days and were liable to produce ptomaine poisoning. Such cases were frequent among that section of the population. In a tenement of three rooms it was quite a common thing to find a family of eight children and perhaps a boarder as well. Dr. Cabaniss had on the night previous to my visit attended a woman in her confinement. There were four of her children living with her at the time in the one room that she possessed. The children were sick the next morning. It also often happens that the patients cannot afford to purchase the drugs prescribed for them. In that case they may appeal to some charitable institution but even if the help is granted considerable time is lost in securing such assistance and the patient suffers in consequence. Others depend when they are ill on sick allowances from benefit or aid societies to which they subscribe; but here, again, some time must elapse before the money is obtained and they are in such extreme poverty that they do not buy the medicine till they have received the sick benefits to which they are entitled. Then there is the pride of the poor which often impedes the efforts of those who desire to help. It appears that among the coloured poor there is a most remarkable amount of pride of this description and therefore much distress remains unknown and unrelieved. These are all causes that contribute to the high death-rate. At Washington the average wage paid to the unskilled coloured worker is 4*s.* a day. Some get a little more or a little less but a dollar is the average. Considering the cost of living this, for America, is a low wage and, of course, is irregular, for often no work at all is to be had.

At Washington perhaps 30 per cent. of the coloured people belong to the better class. Those who have succeeded in raising themselves from the condition of mere labourers seem to do as well as the white man, whether it be as skilled workers, as teachers, or as men of science. In Washington there are a greater number of fully qualified medical practitioners of African descent than there are medical men descended from the European races. Once the negro has acquired superior education he engages in every branch of human activity just as if he were a white man. In regard to medical practice, the coloured practitioner has naturally more practice among the coloured people and this, of course, is the poorest practice. Yet it is not so disadvantageous as it may appear at first sight. The fact is that the poor, while they can only afford to pay very small fees, nevertheless do earnestly endeavour to pay those fees. On the other hand, though the better class of patients pay more when they do pay, it often happens that they do not pay at all. What renders practice among the poorer coloured people especially hard is the fact that they cannot so readily obtain help from the public charities. Cases of cancer are not willingly admitted to the hospitals and cases of pulmonary tuberculosis are absolutely refused. This is a very serious matter indeed for the coloured people, because in their poverty and their overcrowded tenements they have no means of nursing such cases and the close contact with them is more likely to spread the disease. On the other hand, the upper class of the coloured people appreciate sanitary measures, good drainage, and cleanliness quite as keenly as the white population. At least, assurances to that effect were given to me, though I was not long enough in the country to verify these assertions. But even if it were not so there would be nothing surprising or discouraging in such shortcomings. What is surprising is the fact that it is possible already to speak of an upper class among the coloured people. 25 years ago no such class existed. The negro, but recently a slave, was in almost every case an unskilled worker. Now some of them have succeeded in entering even the universities and in competing with the white races as members of the liberal professions. If there is, nevertheless, a much higher death-rate among the coloured population this, I must repeat, is due to economic causes and not to racial inferiority. Not only is this assertion made by coloured medical practitioners but it is admitted by the local authorities themselves. The report of the health officer of the District of Columbia, after giving the comparative vital statistics quoted above, remarks that the suggestion has often been made that the high death-rate of this district is due to the presence of a large coloured population. The report states, however, that—

> The Health Department finds no sufficient basis for the belief that the presence of a large number of people in the District of Columbia who are of African descent is of itself a sufficient cause for a high death-rate. The coloured population of this district represents to a large extent those engaged in severe manual labour, often under conditions involving undue exertion and great exposure to inclement weather. It represents, too, that portion of the community most ignorant of the laws of hygiene and least able by reason of poverty and ignorance to live in accordance with such laws. This is true not only of the present generation but of its ancestors. It is believed that the high death-rate among our coloured people, while possibly due in part to the comparatively recent transplantation of the race to this country, is due largely to defects of constitution produced by long-continued insanitary living and by attacks on such susceptible constitutions by insanitary living at the present time. There is a certain portion of every community subject to the operations of these same causes. The poor and ignorant labouring class in the District of Columbia happens to be more or less distinctly marked out along race lines and its death-rate is therefore separately determined.
>
> The poor and ignorant labouring class elsewhere is usually not of a peculiar race and the mortality in it is not definitely known. Until comparisons have been made between these similar classes of different communities, determined by other than race lines, it seems hardly proper to charge our Afro-Americans as such with the responsibility for an undue mortality. It is unwise, too, to conclude that the death-rate of the District of Columbia is relatively high solely because of the presence of a large number of coloured people in the community. On the other hand, the best interests of the community demand that the most active measures possible be adopted to remove such conditions as are responsible for any undue mortality existing among our poor people as a class, whether white or coloured; such conditions, for instance, as improper housing, lack of facilities for personal cleanliness, and general ignorance of sanitary laws.

The above statement, while confirming the evidence which I was able to obtain from the coloured people themselves, seems so impartial and judicious that I have quoted it at length. The presence of the coloured races really serves to illustrate the great difference of vitality between the extreme poor and the generality of the population. As further illustrating this difference I could not but notice the similarity between the spot maps of Washington published in the same report and many spot maps of the cholera epidemics in various European towns during the years 1892 to 1894. In both cases the incidence of disease corresponded to a large extent with the economic condition of the inhabitants. *The negro problem is therefore the* problem of the unskilled worker—of the submerged tenth, as we should say *in* England. In the south, however, in the old slave States, the position, I am told, is quite different. There it is not, I understand, a question of insufficient wages but of the absolute determination of the negro to live outside the wages system altogether. He seeks to cultivate a little plot of land for himself, to live entirely on his land, and will not work for anyone else, however high the wages may be. Certainly if the negro can live on the soil, if he can afford to keep large towns, factories, mills, and workshops at a distance, and is not attracted to them by the hope of pleasure, dissipation, and gain he may develop an agricultural race of people whose physique will excel that of the town-living white man.

MEDICAL NOTES FROM THE FAR EAST.

(FROM A SPECIAL CORRESPONDENT.)

(Concluded from p. 258.)

THE scenery around Matsuyama is as picturesque as could be wished and the great Daimyo's castle for which it is noted standing out from the trees on the top of the topmost hill, with a magnificent view over 100 miles of land and sea, has been taken over for the housing of the captive Russian officers. At the time of my visit—namely, in August, 1904—there were about 2000 prisoners in Matsuyama, and of these there were then 270 in hospital, almost all suffering from wounds; altogether 670 wounded had been admitted. It speaks well for the Japanese medical men that only seven of these have died (all from the effects of gunshot wounds) and that there has been no death from sickness. Surgeon-General Kikuzi, who was formerly an assistant to Professor Bruns of Tübingen, is in charge of the whole hospital and himself performs all the operations. Two Russian medical men assist in the work of the hospital, one of them, who holds the rank of colonel, taking charge of the medical wards. The Japanese Government has built the hospital and equipped it on generous lines, the complete medical and nursing staff for the 270 patients under treatment consisting of 11 Japanese medical men and the two Russians already mentioned, with 10 male and 66 female nurses, apart from the clerical and menial establishment. The hospital is at some distance from, and out of sight of, the main prisoners' quarters, being situated in rich open country at the end of a village on the outskirts of Matsuyama. The compound is inclosed by a simple wire fence of four strands guarded at the entrance and no doubt elsewhere by a sentry in khaki, but there cannot be much danger of escape. No Russian could be mistaken for a Japanese and in this land of secret information and detectives no European could pass more than a few days without the circumstances becoming known to the authorities. No person of any nationality could well leave the island of Shikoku or, outside of Shikoku, leave Japan without supplying particulars of name, age, parentage, profession, home residence, business, and object of journey to several police officers in turn. At Matsuyama the captured Russians are in safe keeping without obvious imprisonment.

Surgeon-General Kikuzi—"Médecin Inspecteur," as he has h[illegible] his visiting card—is one o[illegible] pan who, with three in [illegible] eral officers under Baron Koike, the Director-General in Tokio. The others who, with Surgeon-General Kikuzi, make up the three in Japan are Surgeon-General Hashimoto at the Red Cross Hospital in Tokio and Surgeon-General Sato in Hiroshima.

The hospital is built, like others, of unstained imbricated wooden boards, has thatched roofs, and is designed on the pavilion principle, the pavilions being connected by a covered central corridor. At one end of it sites are staked out and foundations are being laid for four or six new pavilions, for, as my host remarked with a quiet smile, "we are expecting more guests before long." The infectious ward was away by itself beyond the site of the proposed new pavilions but it was empty. No case of sickness had died, there had been no case of epidemic disease, and there was at the time no case of medical interest in the wards. The latrine system was on the same unreasonable principle as at Sasebo and Hiroshima and need not be again condemned in detail. On the other hand, the Japanese military medical service has an excellent regulation by which the rank and file are given two lectures every month in companies by the medical officers on the principles of health, first aid, and the application of the first field dressing. A corresponding regulation might well be introduced into our army and in order to insure the intelligent execution of sanitary measures it should be laid down as essential that every officer in the army, whether combatant or non-combatant, should have a good knowledge of the same subjects on broader lines. To this regulation the Japanese soldier is now showing absolute submission with the very best results. Similarly in Japanese civil life there is a regulation by which every child in the schools is assigned to the care of a particular medical man whose duty it is to examine and to report on the child's health and physique every year and to give instruction on health matters once a month. In Japan both the Government and the public are making a serious, and in their belief a successful, effort to improve the national physique. In some of the Japanese prefectures (corresponding in size to our counties) there is already a well-organised prefectoral health department. At Nagasaki, for instance, this department consists of 16 medical officers of health who are paid from £70 to £200 a year by the prefectoral government without fixity of tenure and are sent to various districts as may be required.

A good instance of scientific observation in medical subjects being visibly turned to account is the Japanese record of frost-bite during the war with China in the winter of 1893–94. The temperature in Manchuria goes down to −20° F.—i.e., over 50° of frost—and frost-bite during the winter months became seriously common among the Japanese troops. Surgeon-General Kikuzi, however, at that time principal medical officer of one of the armies, observed that frost-bite seldom occurred even at the lowest temperatures so long as the men kept their boots on and remained dry. In driving snow with uncovered hands and ears, or if these extremities were covered only with absorbent woollen materials which became soaked with moisture, frost-bite was of more frequent occurrence and in exposure after crossing a river, as in the battle of the Yalu fought against the Chinese, it was most common of all. The prophylaxis against frost-bite is evidently therefore to [illegible] as dry as possible and [illegible] in the campaign dur[illegible] affords an example of [illegible] must be consulted by any general who understands the importance of health to the efficiency of troops.

At Matsuyama there was a collection of bullets and splinters, the third that I had seen, and one that would well repay examination. The Sasebo collection was essentially one of [illegible] collection was one of Russiar [illegible] was one of specimens of the s[illegible] le the jagged irregular distortion produced by ricochet off rock or stone could be distinguished from the slighter degrees of distortion due to concomitant fracture of a hard bone, and in general an impression was formed that the more slender the bullet the more common is distortion in bulk but the less common is fragmentation. The most remarkable specimen was the complete base of a shrapnel shell, with its cells for the shrapnel intact, measuring six centimetres in diameter and 1·3 centimetres in thickness and weighing 235 grammes, which was extracted, so far as can be remembered, from a pelvic wound with the result that the patient completely recovered. This collection is kept in a glass case in the operation hut together with many interesting pathological specimens preserved in alcohol, chiefly fragments of bone and excised aneurysms of various sorts; the preservation in alcohol has caused a good deal of shrinking and bleaching which might have been avoided by the use of formalin and glycerine. The operation hut consists of three rooms—namely, a well-lighted theatre about 18 feet square, with glass windows along three sides; an instrument room containing instruments, dressings, museum, and sterilisers; and an empty preparation room. Everything was simple, efficient, and cleanly. The only article especially calling for remark was the aseptic dressing invented by Surgeon-General Kikuzi[1] which consists of the charcoal made by burning rice-straw, inclosed in linen bags of three convenient sizes. Straw charcoal is preferred because of its fine division. Rice-straw is used because of the prevalence of rice throughout Japan and China but any straw is equally useful, whether fresh or old, clean or dirty. The straw is simply collected into any convenient iron vessel or in large quantities on the earth, or brick, or stone floor of a room, after which it is set on fire and left to burn itself out in a limited supply of air by covering the vessel in the one case or closing the doors and windows in the other. Bags of ordinary linen, freed from fat and sterilised, are filled with the charcoal under aseptic precautions and the aseptic dressing is complete. Its advantages are that as straw is obtainable almost everywhere it is only necessary to carry the linen bags, that it possesses some bactericidal properties, and that as compared with gauze it is both more absorbent and very much cheaper, costing only one-sixteenth of the price of even the inexpensive gauze made in Japan. In the Mino-Owari earthquake of 1891, when the supply of surgical dressings was cut off for some days by the destruction of the railway, 1600 injured persons were treated with dressings made of rice-straw charcoal at a total cost of 3*s.* 6*d.*

---

[1] Bruns's Beiträge zur Klinischen Chirurgie, Band xxiii.

Among the 670 Russian wounded 22 have been operated on for aneurysm, five of these being arterio-venous lesions and the remainder false or spurious aneurysms of arteries. Six false aneurysms were of the femoral artery. Brief notes of some of the cases were made. In one of them the bullet, as was subsequently found, in passing from side to side through *both thighs must have grazed the front of the right* femoral artery in Scarpa's triangle without injuring the vein. All that was seen at the time of admission was a large pulsating swelling filling the triangle and distending the skin of the limb. On the operating table a very extensive extravasation of blood was found. The femoral artery being controlled in the groin the site of injury of its walls was roughly determined and the vessel was doubly ligatured above and below. The vein was similarly ligatured above and below and the whole tumour with three inches of the artery and vein was removed. The aneurysm had extended right across in front of the femoral vein which, however, was uninjured. The patient had recovered without any untoward sign. There were several interesting cases of injuries of the head, arranged to some extent in series. In one a bullet had entered through the mastoid bone immediately behind the right external auditory meatus, and passing right across the head had made its exit at an almost corresponding position perhaps an inch further back, without causing any symptoms beyond those of local shock. There was not even any headache left and healing had been complete. Another man had been hit half an inch below the inferior edge of the right orbit. The bullet must have passed directly backwards through the malar bone and antrum of Highmore, through the spheno-maxillary fossa and sphenoid bone into the temporo-sphenoidal lobe, and out through the petrous and mastoid portions of the temporal bone. The aperture of exit was just behind the base of the mastoid on the same side. The patient had lost all hearing in the right ear but otherwise he had made a complete recovery. In a third case the wound of entrance was an inch above the left external auditory meatus and that of exit was two inches in front of the right parietal eminence. The injury was incurred on May 1st, 1904, and resulted in a right-sided hemiplegia but this gradually cleared up and finally completely disappeared. In the South African war these side-to-side lesions through the Rolandic area were looked upon as almost invariably fatal. In the present case it was probable that the left motor cortex had alone been injured and that its function had been re-established by the opening up of collateral connexions and by the training of deeper cells to take on cortical functions. There were two or three cases of "fore-and-aft" wounds, one of which must certainly have passed directly through the corona radiata of one side, causing hemiplegia at the time, but recovery was at my visit almost complete. A similar case may be recalled of an officer of the 19th Hussars, seconded to Thorneycroft's Mounted Infantry and hit at Colenso on his first day with his new regiment in a precisely similar way. He was at first completely paralysed on both sides. Six weeks later he was carried on board a hospital ship still almost powerless on one side and finally he was able to walk ashore at the London Docks. Two cases of gunshot wound of the spinal cord were seen. One of these patients was in the low state associated with helpless paralysis on the downward grade. In the other case the bullet had entered beneath the eighth rib in the right flank and had passed apparently through the liver, the vertebral column, and at least the spinal membranes to reach the surface through the muscles of the back on the left side of the eighth or ninth dorsal vertebra. This injury was received on May 1st, 1904, and resulted in total paralysis but after three months the man was able to walk down the ward and back again at marching pace with hardly any dragging of the foot and certainly with no limp. The most probable explanation of this and many similar recoveries is that there had been compression of the cord by a hæmatorrhachis or collection of blood within or outside the spinal membranes and that absorption of this blood allowed the cord to recover its functions.

There were two interesting cases in which a bullet had passed through the brachial plexus, the wound being above the clavicle in one and below it in the other. In the former the man must have had his head almost resting on his shoulder, for the same bullet first passed through the trachea from side to side and thence into the shoulder through the posterior triangle of the neck near its base and out behind. The wounds in the trachea were perfectly healed; the arm appeared to be completely paralysed but the pectoral muscles were not wasted and their function seemed to be retained; the sympathetic was of course uninjured. In the second case the wound of entrance was close outside the coracoid process, while that of exit was below the angle of the scapula of the same side. The musculo-spiral and *ulnar nerves were completely severed but no other nerves* were injured. The general health of this patient has hitherto prevented operation but suture will certainly be attempted as soon as possible. The first-mentioned patient is, I think, to be let alone. To the many instances of wonderful escape may be added one in which the wound of entrance is marked by a small scar in the median line of the neck two inches immediately below the pomum Adami, while the wound of exit is equally small and equally well healed, one inch to the left of the seventh prominent cervical spine. Recovery has been complete.

In one of the wards there was a series of fractures of the femur set in gypsum. As already observed at Sasebo and Hiroshima, they were all well and securely fixed but there was no valid reason why they should not have had the superior advantages of treatment by extension.

Last of all the cases that these letters will have the privilege of reporting in connexion with this war is one that must be unique. When a bullet strikes a bone one of two things may happen, as was proved over and over again in the South African war. Striking compact tissue it may break it, or striking cancellous tissue it may perforate it, breaking it also or not breaking it, according to a variety of other circumstances. Many instances occurred of bullets drilling a clean path through the cancellous epiphyses of the tibia and femur. But here for the first time on record was an indisputable case of drilling of compact diaphysial bone. The bullet had entered behind, and below, the calf of the leg and had issued from the subcutaneous surface of the tibia exactly nine centimetres (three and a half inches) above the tip of the internal malleolus. The skin wound had healed and the depression in the bone could still be felt, with an unruffled surface of bone in a ring all around it. A skiagram in a plane at right angles to the axis of this track would be a very remarkable record. There is, it is said, a specimen in a Paris museum showing a femur cleanly drilled by the new French bullet but it is believed that this lesion was inflicted in a post-mortem experiment.

It was to me an impressive experience after having visited so many Japanese hospitals and inspected the wounds of so many Japanese soldiers and sailors to come to Matsuyama and find myself in a hospital ward before a row of white men, on an average six inches taller than their opponents, saluting and obeying the Japanese surgeon-general. This feeling was even increased on a visit to the officers' pavilion where there were servants, books, cards, and cigarettes, and the patients were gentlemen all, with whom it would have been a pleasure to stay and to talk more than the few available minutes. One of the officers, a Baikal Cossack, spoke English fluently. It seemed to be a curious inversion of conventional notions when Russian officers were led into captivity in Japan.

In conclusion, an apology must be made for the incompleteness of the foregoing notes. Incomplete they must necessarily be, for once only in each case has there been an opportunity of visiting any particular hospital, and that only through the medium of many officials, to whom a great debt of thanks is due. It may be hoped, however, that enough has been said to stimulate public interest in the *official* reports of Lieutenant-Colonel W. G. Macpherson, R.A.M.C., British attaché with the Japanese forces now in Manchuria, and in the report of the Japanese naval and military medical services which is expected to appear after the conclusion of the war

BIRMINGHAM

(FROM OUR OWN CORRESPONDENT)

University Intelligence

Dr R Saundby, professor of medicine in the University, has promised to give a course of lectures upon Medical Ethics to medical students and practitioners during the summer sessions —Dr Edward Malins professor of midwifery, has been appointed examiner in midwifery and diseases of women in the Victoria University, Manchester —Dr A Stanley Barnes, Dr J T Hewetson, and Dr Thomas Wilson have been re-appointed honorary curators of the pathological museum of the University

"Humanised' Milk

The report of the deputation from the health committee of the city council which recently visited Liverpool for the purpose of making inquiries into the method there adopted of supplying ' humanised ' milk was considered at the last meeting of the above committee In view of the good results as shown in the marked diminution of the infantile mortality rate claimed for it by the Liverpool authorities it was decided to introduce a similar system into Birmingham and a subcommittee was appointed to confer with the dairy men in the district in order to ascertain whether they would undertake to supply such milk or whether they had any suggestion to make in reference to the provision of such milk by the city authorities The *Daily Post* dealt with the matter in a leading article in which it deprecated any further experimentation in the direction of municipal trading and was of opinion that the supply of the milk might very well be left to private enterprise Considerable correspondence followed in the public press The opponents of the scheme observed that "humanised' milk was milk devoid of antiscorbutic qualities and that its introduction would tend still further to diminish the amount of breast feeding among the masses The rejoinders were that it is unsatisfactory to leave the "humanisation" of the milk to the mothers who are often ignorant and careless, that it is well nigh impossible to obtain pure milk and to keep it pure that the less trouble and expense associated with breast feeding will prevent any further decrease in its practice, and that the introduction of such a supply as that now meditated has been largely responsible for the decided fall in the infantile mortality rate at Liverpool

The Hospitals

Mr Wilfrid Allport who for the last five years has acted as honorary assistant ophthalmic surgeon to the Queen s Hospital has been elected honorary ophthalmic surgeon to the same institution in the place of Mr J Priestley Smith who has resigned —The new buildings of the Birmingham and Midland Hospital for Women are rapidly nearing completion The new convalescent home in connexion with it was opened on Feb 4th before a large and distinguished company by the Right Honourable the Countess Beauchamp The home, which is situated a short distance from the main buildings at Sparkhill is a picturesque house of two storeys with accommodation for 12 patients At its opening Mr J S Nettlefold chairman of the committee of management made a strong appeal for a further £10 000 in order that the main building might be opened free from debt It is estimated that the entire cost of the hospital will amount to £40 000 of which sum more than £30 000 have already been promised The hospital will afford accommodation for 1000 patients per annum

The Birmingham Corporation and the Wye

The act [illegible] ig to reduce by [illegible] ater which, by [illegible] was discussed by the Severn Board of Conservators at its last meeting The suggestion of the chairman was adopted that a deputation should be appointed to wait upon the Board of Agriculture and Fisheries and to object to the proposed reduction on the ground that any further abstraction of water would be injurious to the fisheries of both the Wye and the Severn

The Health of the City

The report of the medical officer of health for the final quarter of 1904 has just been published The birth rate was slightly lower than it was in 1903, the death rate was the same in the two years The zymotic death rate was low but the mortality from respiratory diseases was high Although the cases of diphtheria reported were less numerous than usual the death rate was high, this was attributed to parents not sending for medical help early enough and to insufficient use of antitoxin, only 33 per cent of the patients apparently were treated with antitoxin supplied by the municipality It was pointed out that the cases of typhoid fever were few despite the fact that the summer was long warm and dry, this was taken as indicating that some of the conditions favourable to its development have been removed Deaths from diarrhœa were relatively few and each was made the subject of an inquiry by one of the health visitors The death rate for the week ending Jan 21st was 19 per 1000 as compared with 19 8 for the preceding week, for the week ending Jan 28th it was still further lowered to 16 5 The zymotic death rate remained steadily about 1 per 1000 There has been a slight increase in the number of cases of scarlet fever and diphtheria notified The number of patients in the typhoid fever wards has been reduced to nine

Severe Outbreak of Measles in Wednesbury

The epidemic of measles which has recently visited Wednesbury has proved to be of a virulent type, of the 94 deaths from all causes during the last six weeks no less than 41 were attributable to this disease

Feb 7th

LIVERPOOL

(FROM OUR OWN CORRESPONDENT)

Annual Report for 1904 of the West Derby, Liverpool, and Toxteth Park Joint Hospital for Phthisis at Heswall

THE annual report consists of three reports by the medical officers of the three unions to the Heswall joint committee and also the report of Mr H P Cleaver, the clerk Each medical officer was only allowed to report on his own cases In the medical management of the hospital each medical officer sends in his own cases without reference to his colleagues All cases must have had tubercle bacilli found before admission The medical officers are on duty in rotation a month at a time, during that time the medical officer on duty is responsible for all patients examines and discharges them prescribes the treatment, and takes notes He places in the hospital record his opinion of the case on discharge A medical officer who is not on duty may visit the hospital to examine his own cases The clerk s report shows the cases in detail with the hospital discharge and the initials of the medical officer discharging, also the results of sputum examination (all done at the Thompson Yates laboratory) any news of after results which has reached the hospital and the report of a special non medical visitor who was sent round in December last to follow up the cases Dr Nathan Raw s report on the cases admitted from West Derby states that 34 patients were under treatment during the year In ten cases the disease was arrested 12 were improved two were not improved, whilst ten remained in the sanatorium There was no death in the sanatorium during the year Some of the patients have continued at their work since leaving the sanatorium and report themselves to him at intervals while others have left the neighbourhood and he has lost sight of them The sanatorium continues to do the good work for which it was provided There has been during 1904 a decided improvement in the character of the admissions most of them being amenable to treatment and it cannot be impressed too strongly that the treatment to give the best results must be commenced in the early stages of the disease The sanatorium performs a humane and economic work amongst the poor It rescues some from certain death it relieves the suffering and prolongs the working life of others whilst it isolates them all from their ordinary home surroundings thus preventing the spread of infection to healthy members of the family It also acts as [illegible] aching the patients the nature [illegible] methods of resisting its attack. [illegible] union Dr David Smart reports useful, whether fresh or old, clean or dirty. The straw is simply collected into any convenient iron vessel or in large quantities on the earth, or brick, or stone floor of a room, after which it is set on fire and left to burn itself out in a limited supply of air by covering the vessel in the one case or closing the doors and windows in the other. Bags of ordinary linen, freed from fat and sterilised, are filled with the charcoal under aseptic precautions and the aseptic dressing is complete. Its advantages are that as straw is obtainable almost everywhere it is only necessary to carry the linen bags, that it possesses some bactericidal properties, and that as compared with gauze it is both more absorbent and very much cheaper, costing only one-sixteenth of the price of even the inexpensive gauze made in Japan. In the Mino-Owari earthquake of 1891, when the supply of surgical dressings was cut off for some days by the destruction of the railway, 1600 injured persons were treated with dressings made of rice-straw charcoal at a total cost of 3*s.* 6*d.*

Among the 670 Russian wounded 22 have been operated on for aneurysm, five of these being arterio-venous lesions and the remainder false or spurious aneurysms of arteries. It may be hoped, however, that enough has been said to stimulate public interest in the official reports of Lieutenant-Colonel W. G. Macpherson, R.A.M.C.,

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

University College, Bristol.

THE sixth annual dinner of the University College Colston Society was held in the large hall of the college on Jan. 31st. Dr. Butler, the master of Trinity College, Cambridge, who was one of the guests, referred to the question of the compulsory teaching of Greek. He said that there was perhaps no man living more bound to the Greek language and literature than he was. Yet he had found by experience and by comparing notes with others that however magnificent the results of the study of the Greek literature, language, poetry, and philosophy might be in the case of those who loved Greek and for whom it might be presumed to be well fitted, there was, nevertheless, a very large body of industrious boys for whom it was too heavy a burden if they were also to learn Latin seriously and to take up the many branches that were grouped under the name of "modern subjects."

Aberystwith Infirmary.

The Aberystwith Infirmary and Cardiganshire General Hospital was established as a dispensary in the year 1821 and indoor patients were first taken in for treatment in 1838. At the annual meeting of the subscribers to the institution held on Feb. 4th it was stated that the income of the past year had been sufficient to meet the expenditure but regret was expressed at the scanty support given to the infirmary.

The Unemployed in Bristol.

Early in the year arrangements were made by the Bristol sanitary committee to give employment to men out of work and the city engineer has just reported that up to the end of January applications for work were received from 2502 men, of whom 1748 were notified that work would be found for them, and of this latter number 1236 responded and were given work. An important conference upon the questions of vagrancy and the unemployed was held in Bristol on Feb. 3rd under the presidency of the Right Hon. Lewis Fry. A very thoughtful contribution to the subject was made by Mr. J. J. Simpson, the clerk to the Bristol board of guardians. He stated that the official census of those sleeping in the casual wards of the 645 unions throughout England and Wales showed that for some years prior to 1900 the number was stationary at rather under 5000 but year by year since then there has been a steady increase until last year there were 7634 on a given date. Of these, 87½ per cent. were men, 10 per cent. were women, and 2½ per cent. were children. With a view to ascertain the proportion of actual vagrants returns were obtained of the total number of tramps sleeping in the Gloucestershire and Somersetshire workhouses on the night of Jan. 28th, 1905. These amounted to 448, of whom 274, or 61 per cent., were considered by the union officials to be workmen in search of employment. Mr. Simpson is of opinion that these *bonâ-fide* workmen should still be given food and shelter by the boards of guardians but that the cost should be defrayed by the State, thus insuring uniform treatment. The tramp who will not work, he suggests, should be sent to, and detained in, a labour colony. After some discussion the conference passed a resolution expressing the opinion that destitute working men compelled to seek employment should not be associated with vagrants but should receive maintenance and aid in their search for work and that the vagrants and unemployable should be detained in labour colonies provided or subsidised by the State and open to the inspection of officers of the State appointed for the purpose.

Death from an Electric Shock.

To the more familiarly known risks attending the working of collieries must now be added those attached to electrical installations working at a high voltage, for electricity is now rapidly superseding othe [illegible] of coal mines. A man in [illegible] engine in one of the collieric [illegible] Company was recently four [illegible] his back quite dead. On c [illegible] hand there was a burn of about the size of a florin and on the right side of his forehead there was another burn an inch broad at its broadest part and tapering off to about three inches long. No other marks of injuries were found and it is surmised that he met his death owing to a leakage from the plant which was on the alternating system and worked up to a voltage of 600.

Death of Mr. Charles Pegge.

The death occurred at his residence, Baglan House, Briton Ferry, on Feb. 4th, of Mr. Charles Pegge, M.R.C.S. Eng., L.S.A., at the age of 73 years. Up to a few years ago Mr. Pegge was the proprietor of the Vernon House Lunatic Asylum in Briton Ferry, which was at one time the only institution of its kind in Glamorganshire. He was closely identified with the local industries and was for many years medical officer of health of the district, a position now held by his son, Mr. E. Vernon Pegge.

Devon and Cornwall Ear and Throat Hospital, Plymouth.

The eighteenth annual meeting of the subscribers to this institution was held on Feb. 3rd under the presidency of the mayor. The medical report stated that 885 patients were treated during 1904, as compared with 652 in 1903. The financial statement showed that at the end of 1903 there was an adverse balance of £13, which in 1904 was converted to a favourable balance of £22.

Feb. 6th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

Death of Dr Thomas McKay Youngson.

HIS many student and other friends will hear with regret of the death of Thomas McKay Youngson, M.B., C.M. Aberd., which occurred at Longport, Staffordshire, on the morning of Jan. 29th. A son of the late Mr. James Youngson of Aberdeen, Dr. Youngson studied medicine at Marischal College and graduated in 1893. In the course of his college career Dr Youngson gained several prizes. He was a young man of frank and genial disposition and was very popular with his fellow students. After graduating he commenced practice at Longport where he was successful and gained much popularity. Dr. Youngson held the office of medical officer of health of Wolstanton. He had recently been in somewhat feeble health and his death at the early age of 33 years will be mourned by many friends. Dr. Youngson married an English lady by whom he is survived.

Aberdeen Royal Infirmary.

The annual report of this infirmary shows that the number of patients received during the past year was 840 in the medical wards and 1859 in the surgical wards, making altogether 2699. The total number of cases treated was 917 medical and 1989 surgical, making a total of 2906 cases. Of these there were discharged—recovered, 1235; improved, 949; unfit or at desire, 286; died, 217; making a total of 2687; and remaining in the hospital on Dec. 31st, 219. The average daily number of occupied beds was 217—the highest being 244 on March 18th and the lowest 189 on July 24th. The average number of days in hospital of each patient was 27·3. The operations performed on in-patients numbered 1546. The death-rate was about 7·5 per cent. of the cases treated. The deaths which took place within 48 hours after admission numbered 51, having mostly occurred in cases of severe injury or of a hopeless nature. Deducting these from the total number of deaths the rate is reduced to about 5·7 per cent. Compared with the preceding year the cases treated showed an increase of 166. The average number of beds occupied remains the same but the average period in hospital of each patient is reduced by 1 5 days. The number of operations has increased by 291. There were 12,715 out-patients who received advice and treatment, being an increase of 1827 over the numbers for last year. The rapid increase in out-patients is forcing upon the board the question of extended accommodation in this department. The very large number who accept the services of the hospital in both in- and out-patient departments bears testimony to the confidence reposed in the infirmary by the public. The following is an abstract of income and expenditure for the year: ordinary income, £11,254 15*s*. 3*d*.; ordinary expenditure, £11,937 3*s*. 6*d*.; deficit on ordinary account, £682 8*s*. 3*d*.; extraordinary income (legacies, &c.) available for current expenses, £365 11*s*.; deficit for 1904, £316 17*s*. 3*d*.

Feb. 6th.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

Royal Victoria Hospital, Belfast.

THE old Royal Hospital has been let for a tourists' hotel, with the result that an income of about £400 per annum will be secured for the funds of the new institution. The receipts for the year 1904 have exceeded the expenditure by about £700 and, the prospective income being good, notice has been given that at the next meeting of the board of management a motion will be proposed to open another "unit"—that is, a male and a female ward each with 16 beds, making 32 in all. It is calculated that £1000 will maintain a unit.

Health of Belfast.

A very large and influential deputation appeared before the city corporation on Feb. 1st to protest against the sewage from the new infectious diseases hospital being conveyed into the ordinary sewers. The chairman of the public health committee, in reply, said that the sewage from this place would pass through disinfecting tanks and would be thoroughly disinfected before being pumped into the general sewer and that the excreta from the small-pox hospital would be burned in the incinerator. Further, he said that those who objected to this plan of conveyance of the drainage could suggest no alternative scheme, to which the deputation reply that it is none of their business but the duty of the city authorities who built the hospital and who could call in expert advice. He also said that the sewers from the union infectious diseases hospital opened into the public sewers of the city, the reply to which is that this is the remains of an old system which no public health authority would tolerate now and offers no excuse in the case of a new up-to-date infectious diseases hospital; besides, if there is any weight in such an argument, why disinfect at all the sewage from the new infectious diseases hospital? But, as explained at the meeting of the city corporation, when this question was discussed on Feb. 1st, by Alderman Harper (a leading solicitor in Belfast), it is doubtful whether the Belfast corporation can legally bring one particle of sewage from Purdysburn in County Down, outside the city area, through the city sewers and tip it at the entrance to Belfast Lough. He pointed out that the privilege of bringing sewage and emptying it into Belfast Lough was given to the council by Act of Parliament on the clear understanding that it was to be submitted to bacterial treatment and, in the face of recent investigation on that subject, no one could deny that this had not been done. If the council had not up to the present taken precautions to treat bacterially all the sewage already being discharged into Belfast Lough (as it was bound to do by Act of Parliament), why should it add to this the dejecta from patients in an infectious diseases hospital outside its area in another county? The question is one surrounded with difficulties and after a long discussion it was decided to call a meeting of the corporation to deal with the whole subject. At a further influential meeting of citizens held on Feb. 6th it was pointed out that before making new sewers or sewerage works three months' notice should have been given in the daily press and it is alleged that no such notice has been given in the case of the sewers from the infectious diseases hospital. Typhoid fever is gradually decreasing, scarlet fever of a mild type still prevails, and the number of cases of small-pox remains about the same.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Unqualified Medical Practice in Germany.

THE Government Medical Department has undertaken an investigation into the conditions of unqualified medical practice which is not illegal in Germany provided that certain limitations are observed. The requisite details were collected by the local medical officers of health and the newspapers have published some remarkable evidence with reference especially to the training of the practitioners in question. It appears that more than 75 per cent. of them have received only such general education as is given at a common school, while their professional training is so imperfect that only a few have any knowledge of medicine, these being for the most part men who had formerly been either pharmaceutical chemists or else medical students who had failed to pass the examinations. In the same category may also be placed persons who had formerly been nurses, attendants, or servants either in hospitals or in the employment of medical men. The report states that in some country places there are families which for generations have treated accidents, fractures of bones, and sprains, and in these families such medical knowledge as they possess is transmitted from the older members to the younger ones. This is especially the case in the families of shepherds who have an extensive practice in certain districts. Some of the unqualified practitioners declared that they had learned the theory of the subject by reading scientific books or by attending scientific or popular lectures. It must further be mentioned that there are colleges founded and supported by certain societies where students may obtain some medical training and even a diploma but the latter is of course not recognised by the authorities. It is said in the report that a good many of these practitioners had made previous trial of several other professions before devoting themselves to medical work as a last resource. Moreover, in addition to the quack practitioners there are in country places a good many persons belonging to the educated classes, such as clergymen and their wives, teachers, property owners, and others, who distribute medicine to the disadvantage both of the medical profession and of the patients.

Death of Professor Abbe.

Professor Abbe, who died in Jena a fortnight ago, though not a medical man, nevertheless contributed in a remarkable degree to the progress of medical science, for the high stage of development which microscopy has now reached is largely due to the scientific spirit and the technical skill which were combined in him. Professor Abbe began his career as a *privat-docent* at the University of Jena. At that time Herr Zeiss had in the town a fairly good business as a maker of microscopes and other optical instruments, and Professor Abbe was engaged by him for the purpose of making the optical and mathematical computations which are so necessary in that description of work. While thus engaged he devised the forms of achromatic condenser and object-glass which bear his name, improvements which gave a great impetus to bacteriology and enabled important advances to be made in many other directions. He subsequently became a partner in the firm which through him had acquired a worldwide renown and in 1888 he was left sole proprietor, whereupon the spirit of philanthropy and self-abnegation which was so marked a feature of his character induced him to forego his rights of ownership and to devote the proceeds of the business to promoting the welfare of the community. The Zeiss Optical Works were accordingly changed into a sort of public institution managed by a committee and the profits were utilised (1) for the benefit of the 2000 workmen employed in the factory who became in some degree partners in the business; (2) for the advancement of science; and (3) for the benefit of the general population of Jena. The workmen shared in the profits, their daily hours of work were shorter than at any other factory, and their official and compulsory assurance was supplemented by additional assurance against want of employment and other difficulties. A library, a reading room, and other institutions for the use of the inhabitants of Jena were also provided and the teaching of science was aided by the establishment of lavishly furnished laboratories in the University. It is decidedly unusual for the owner of a very lucrative business voluntarily to surrender the profits derived from it. Professor Abbe, however, preferred to occupy the position of an employé of his own factory, drawing a small salary which was no more than sufficient for a modest livelihood.

Etiology of Scarlet Fever.

Dr. Siegel of Berlin, writing in the *Medicinische Klinik*, states that he has discovered in the blood of patients suffering from scarlet fever small gelatinous discs containing a nucleus but not possessing the faculty of spontaneous locomotion. On staining the preparation with eosin blue the nucleus becomes visible in different stages of division, varying from simple bisection to disintegration into motile spores. In rabbits which have received injections of blood taken from scarlet fever patients the above discs appear in the liver, the kidney, and the spleen. They belong to the protozoa and in some respects, though not in all, they are very like the corpuscles of vaccine lymph.

Feb. 6th.

EGYPT.

(FROM OUR OWN CORRESPONDENT.)

The Egyptian Government Medical School.

THE annual dinner of the members of the staff has just taken place and was attended by the 15 teachers, all of whom are now Englishmen with the exception of three Germans and one Egyptian. The guest of the evening was Dr. W. St. C. Symmers who is this week resigning the chair of pathology here for that at Queen's College, Belfast. His colleagues seized the occasion to present him with a large silver bowl and H.H. the Khedive has graciously expressed his intention of conferring a decoration upon him. Among the guests were Mr. Reginald Harrison and Professor Arloing, the well-known veterinary expert of Lyons, who has been sent here by the French Government to study the various diseases which affect cattle in this country. It is wonderful what progress the medical school has made since it passed into European hands. In 1890 the only European teacher was a Frenchman who knew no Arabic which was the only language understood by the students. Now, only 15 years later, the students are all conversant with English, pursue their studies with the aid [illegible] museums are slowly growing, and laboratories attract workers from Europe. In this school Dr. G. Elliot Smith has discovered an interesting confirmation of the Darwinian theory while working at the brains of the Soudanese and the Egyptians and Dr. Looss has proved to the satisfaction of all that ankylostoma embryos can, and do, enter the human body by means of the skin. But the one dark spot of the School of Medicine is the almost complete absence of European assistants. The Egyptian Government for many years has had the excuse that money was not forthcoming for all reforms but now that means are provided assistants should be furnished at once to those who are engaged on scientific research which adds to the knowledge of the whole civilised world. In most colleges senior students can be trained to act as demonstrators and assistants under their professors but in Egypt this is at present impossible because the Sanitary Department, menaced by plague and other epidemics, needs the services of all available graduates directly they are set free from the hospital.

Cairo, Jan. 30th.

CANADA.

(FROM OUR OWN CORRESPONDENT.)

Toronto General Hospital.

The annual report of the Toronto General Hospital for 1904 shows that 12,984 persons received medicine and treatment at either the hospital proper or at its emergency branch in the very heart of the city. In that time 3397 patients were admitted into the wards, which with 260 patients in that hospital at the commencement of the year and 154 births, made a total of 3811 receiving attention in the institution in 1904. The number of patients in the hospital in the month of December, 1904, was 576, of whom 272 were discharged, while 22 died, leaving 282 in the hospital on Jan. 1st, 1905. In December 277 accident cases were attended to at the emergency branch.

Infectious Diseases in Toronto.

The medical officer of health of Toronto, Dr. Charles Sheard, has compiled some interesting statistics and comparisons for 1904 and 1903. In December, 1903, there were reported 173 cases of diphtheria, 23 cases of scarlet fever, and 16 cases of typhoid fever; for 1904 the numbers were respectively 227, 50, and 14. The total number of cases reported for the years were as follows: 1903, diphtheria, 1103; scarlet fever, 699; and typhoid fever, 156; for 1904, diphtheria, 1360; scarlet fever, 318; and typhoid fever, 138. The deaths were: for December, 1903, diphtheria, 21; scarlet fever, 3; and typhoid fever, 2; for 1904, 17, 1, and 6. In the returns for 1904 the number of deaths from scarlet fever is shown to be the lowest in six years. The decrease was from 100 in 1903 to 12 in 1904. The total deaths in 1904 from these diseases were as follows: diphtheria, 125; scarlet fever, 12; typhoid fever, 41; and small-pox, 2.

Canadian Medical Association.

The thirty-eighth annual meeting of the Canadian Medical Association is to be held this year from August 22nd to 25th at Halifax, Nova Scotia, under the presidency of Dr. John Stewart of that city. Mr. Francis M. Caird of the Royal Infirmary of Edinburgh has promised to deliver the address in surgery. Dr. Howard Kelly of Baltimore, U.S.A., will deliver the address in gynæcology and Dr. J. W. Stirling of Montreal will deliver an address in ophthalmology. In addition to these there will also be addresses in medicine and pathology. The members of the Medical Society of Nova Scotia will not hold their annual meeting this year but will act as hosts to the members of the Canadian Medical Association. Seeing the start that has already been made it is quite safe to say that this meeting of the association will equal the average of recent years.

Physicians Scarce in Newfoundland.

A correspondent writes to the *Montreal Star* from St John's, Newfoundland, that in the remote regions of the Newfoundland coast there is great want of proper medical attendance for the fisher folk. It is said that for hundreds of miles in some sections physicians have to go by special boat or schooner to attend upon the sick of these settlements. The hardships have been so great and the mortality so severe that the government of the island has taken the matter up and are appointing physicians to the magistrates of the different townships, with an allowance of $500 per annum, hoping in this way to induce physicians to settle in these out-of-the-way sections.

Resignation of a Veteran Medical Teacher.

Senator Michael Sullivan, M.D., has resigned his position as professor of surgery in Queen's University, Kingston, Ontario, after a service of 50 years. When the medical department of Queen's University was founded Dr. Sullivan was one of its first students and he has been connected with it as tutor, lecturer, and professor for half a century. His jubilee will be celebrated in April at the annual college convocation. At that time he will be honoured by being made honorary professor of surgery and the degree of LL.D. will be conferred upon him.

Canadians and General Laurie's Amendment to the Medical Act.

Through delay in mails General Laurie's amendment to the Medical Act, which was before the British House of Commons last session, was not before the last annual meeting of Canada's national medical organisation, the Canadian Medical Association, but the matter has been brought before the representative city and local societies in order that General Lauri [illegible] from the Canadian [illegible]. So far as I kno [illegible] the St. Francis District Medical Association of the eastern townships of the province of Quebec, which at its regular meeting on Jan. 14th passed a motion supporting the proposed amendment to the British Medical Act of 1858 whereby medical men of this country may be competent to enter the navy and the army on the same footing as those educated at the British colleges.

The New Ontario Medical Library.

Dr. Osler came from Baltimore and spent the last week of 1904 with his Toronto friends and was entertained by his medical friends in this city. On the afternoon of Dec. 29th he formally opened the new home of the Ontario Medical Association, towards which residence he had himself contributed many volumes and $1000. The library starts well in its new home, the total cost of the building, some $10,000, having been raised through the efforts of the President, Dr. J. F. W. Ross, and the honorary librarian, Dr. N. A. Powell.

Jan. 23th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Mortality among Physicians.

AN interesting account of the mortality among physicians appears in the *Journal of the American Medical Association.* The statement embraces the record of 2142 physicians who died during the year 1904. The ages of these physicians varied between the limits of 22 and 104 years, the average being about 60 years. The greatest number of deaths occurred at the age of 60 years, the next greatest number at the age of 70, the next at 65, the next at 67, and the next at 75. Above the age of 70 years there were 596 deaths; above the age of 80 years, 241 deaths; and above the age of 90 years, 19 deaths; three had passed the age of 100 years. The greatest age recorded was 104 years. Heart disease heads the causes of death with 205; cerebral hæmorrhage caused 179 deaths. Pneumonia heads the list of clearly defined *diseases with 172 deaths, or 7·5 per cent. of the total* mortality. There were 36 suicides, 14 by poison and 11 by firearms. The rate of mortality was 17·14 per 1000. The average length of practice was 30 years.

A Novel Form of Heresy in Court.

The Supreme Court of Michigan had recently before it what it calls a novel case. The defendant was a teacher of Eddyism and first reader of the First Church of Christ, Scientist, of Detroit. The declaration stated that the defendant was supposed to be a conscientious believer in, and practiser of, the principles of "Christian Science" and mentally and morally qualified and competent to give class instruction in "Christian Science mind healing"; that the plaintiff agreed to pay, and did pay, the defendant $100 for instruction which was given; that by reason of the defendant not being a sincere and faithful believer in, and practiser of, Christian Science the plaintiff received no benefit from the instruction given him; wherefore he sought to recover the money paid and compensation for the time spent in the attempt to learn "to cure disease through the power of Christian Science mind healing." It appeared at the trial that the defendant had had superfluous hair removed from her face by a physician by electrical treatment two or three years prior to the contract with the plaintiff, and as the plaintiff was able to call a medical expert who testified that the superfluous hair was known to pathology by the name of "hypertrichosis" and was a disease, and as Eddyism is opposed to material treatment for disease, the court held that one who had superfluous hair removed was not a true believer in, and adherent and practiser of, the principles of Eddyism. But apart from the consideration that this departure from the true faith, if it be such, occurred two years before the *contract with the plaintiff, thus leaving ample time for the* defendant to mature her belief, the court deemed it sufficient answer to the plaintiff's contention that, if it be conceded that superfluous hair was a disease, it was also regarded by many as a facial blemish; some concealed it as well as they might by the use of face powder and some had it removed. The defendant, because her little son teased her about the appearance of this superfluous hair, caused it to be removed. This was not done as a treatment of disease but as a means of making herself more presentable. The court thought this did not tend to show that the defendant was guilty of fraud in holding herself out as a teacher of Eddyism. The court added that it was understood that both the plaintiff and the defendant proceeded on the theory that Eddyism, as taught by Mrs. Eddy's book, "Science and Health," was true and that it had determined the case on that assumption. The judgment was in favour of the defendant.

A National Quarantine.

The President of the United States in his recent annual message recommends the passage of a law creating a national quarantine. This is one of the most important steps taken in this country towards perfecting a national *system of sanitary administration. The great obstacle to* progress in creating a national system has been the doctrine of State rights so tenaciously held by the forefathers. In modern times the tendency has been to enlarge the powers and jurisdiction of the general Government in regard to all questions relating to inter-State commerce, and the advantages accruing to the States by the assumption of such duties on the part of the national Government have proved so great that there is less opposition than at any other period in the history of the country to the proposition that the quarantines of the several States should be placed wholly under the control of the Washington Government. The present seems to be a most fitting opportunity to effect this reform. The utter worthlessness of the old quarantines, as conducted by the States, has been abundantly shown, while the few quarantines conducted by the authorities of the public health service at Washington have been of the highest efficiency.

Incorporation of the American Medical Association.

A Bill has been introduced into Congress to incorporate the American Medical Association. The object of the Bill is to give more weight and character to the association in all medical matters that come before Congress. The association now represents the entire medical profession of the country and is in a position to exercise great influence on all questions of a national character, as in the promotion of public health reforms, the improvement of the medical department of the army and the navy, and the advancement of the science and art of medicine. But to be effective in its efforts the association must be placed among the institutions which have an incorporation under the general Government.

Reform in the Medical Department of the Army.

So great has become the necessity for reforms in the Medical Department of the Army that the President has sent an urgent message to Congress in favour of a Bill making sweeping changes in this service. Accompanying the message is a memorandum by the Surgeon-General which details at length the needs of the service. The commissioned *personnel* of the Medical Department is nearly 200 short of the required number to perform its work at present and the deficiency has to be made good by the employment of civilian physicians under contract. This is an expensive and unsatisfactory expedient in time of peace, while in time of war it heavily handicaps the efficiency of the department. The Surgeon-General states that in the war with Spain the country was scandalised by a monthly death-rate from disease which rose from 2·15 per 1000 in July to 4 08 per 1000 in August. He adds: "The public sentiment of the civilised world demands a better organisation and higher efficiency for the medical department of armies than at any time heretofore." The President remarks: "If the Medical Department is left as it is no amount of wisdom or efficiency in its administration would prevent a complete breakdown in the event of a serious war."

Jan. 27th.

Medical News.

University of Oxford.—The following degrees have been conferred:—

B.M., *B.Ch.*—Richard Harvey Sankey, Christ Church; John Freeman, University College; John Alexander Vlasto, New College; Eric MacLeod Smith, Queen's College; Edward How White, University College; Arthur Williamson Brodribb, University College; and Archibald Henry Hogarth, Christ Church.

University of Cambridge.—The voting on the proposals of the Studies and Examinations Syndicate respecting the previous examinations will take place in the Senate House on March 3rd and 4th between the hours of 1 and 7 P.M. The syndicate has issued an amended report in which, however, the proposal to allow modern languages to be substituted for Greek is retained.—At the Congregation on Feb. 2nd the following degrees were conferred:—

Doctor of Medicine.—S. H. Nathan, Trinity; A. J. Hall, Caius; and S. W. Curl, Downing.

Master of Surgery.—A. R. Brailey, Downing.

Bachelor of Medicine.—T. C. Lucas, Clare; and C. W. Cunnington, non-collegiate.

Bachelor of Surgery.—L. Dukes, Trinity; R. C. Mott, Trinity; and C. W. Cunnington, non-collegiate.

Trinity College, Dublin.—At examinations held in Hilary term the following candidates were successful:—

Previous Medical Examination.

Anatomy and Institutes of Medicine.—Archibald L. Robinson, George H. Stack, Eleanor E. Finegan, John W. Lane, and Wallace D. Mitchell.

Physics and Chemistry.—John G. W. Ponton, Samuel Swinburne, and Charles O'Brien.

Botany and Zoology.—Henry E. M'Cready, John Murdoch, Charles H. O'Rorke, Richard D. FitzGerald, and Wellesley R. Allen.

Foreign University Intelligence.—*Bern:* Madame Schwenter-Trachsler, M.D., has been recognised as *privat-docent* of Dermatology and Syphilis.—*Bologna:* Dr. Guido Ruata has been recognised as *privat-docent* of Hygiene.—*Bonn:* Dr. Hugo Selter has been recognised as *privat-docent* of Hygiene.—*Breslau:* Dr. G. Baerman has been recognised as *privat-docent* of Dermatology.—*Cracow:* Dr. Stanilas Droba has been recognised as *privat-docent* of Bacteriology.—*Lemberg:* Dr. Heinrich v. Halban has been appointed Extraordinary Professor of Mental and Nervous

Diseases —*Lund* Dr Karl M Furst has been promoted to the Ordinary Professorship of Anatomy with the post of Director of the Anatomical Institute —*Pavia* Dr Riccardo Galeazzi of Turin has been recognised as *privat docent* of Surgery and Operative Medicine —*Pisa* Dr Leone Sestini has been recognised as *privat docent* of Hygiene

ROYAL INSTITUTION —A general monthly meeting of the members of the Royal Institution was held on Feb 6th, the Duke of Northumberland, the President, being in the chair Lieutenant Colonel H E Gaulter, Mr E P Harvey, Mrs Ludwig Mond Dr Tcherniac, and Dr Evelyn C B Wilbraham were elected members

THE HOME OF RECOVERY —A dinner will be given at Prince's Restaurant, Piccadilly, London, W , on Feb 16th for the advancement of this new home It is of course, true that the homes already in existence are legion but those homes which receive and treat patients with wounds or sores not yet healed are not legion, and are indeed too few for the work to be accomplished These cases block the hospital beds and exclude patients in urgent need of admission , they get no particular benefit from confinement in hospital, they are not instructive to students, and they keep out more deserving cases The Home of Recovery is intended to take these slow unhealed cases which are refused at the great majority of our convalescent homes

MEASURES TO PREVENT THE IMPORTATION OF DISEASE INTO RUSSIA —The chief medical inspector, Professor Anrep, according to the *Svet*, has made a journey on the Siberian Railway for the purpose of clearing up the question of how to prevent the conveyance of disease from the Far East into European Russia He went as far as Tchita and came to the conclusion that the sanitary trains in which the sick are conveyed are in most cases splendidly fitted and possess a sufficient supply of disinfectants and other necessary material A danger is possible in the movement of reserves, whether discharged or in process of moving from one place to another This, he thinks, may lead to undesirable consequences and shows the need for special quarantine stations Such a station it was proposed to establish at Tchita , this town, however, was found to be unsuitable and a position between Irkutsk and Tchelyabinsk is now suggested

STREET AMBULANCES FOR LONDON — At the usual fortnightly meeting of the Metropolitan Asylums Board held on Feb 4th a letter was read from the London County Council, with reference to the letters from the Metropolitan Asylums Board of Nov 29th, 1904, and Jan 25th, 1905 in connexion with the proposed conference between a committee of the Council and the ambulance committee of the Asylums Board on the subject of the suggested ambulance service for London The letter stated that the extent of the desirableness of undertaking the supervision and management of an ambulance service for the convenience of street accident cases was still under the consideration of a committee and it was to be hoped that a report would be made to the Council on the subject at an early date The letter further stated that at the present moment the question of undertaking the conveyance of cases other than those arising from accidents and casualties in the streets was not under consideration and that it would therefore appear that any action which the Council might take would have regard to different classes of cases from those of mental, medical and surgical patients with which the Metropolitan Asylums Board intended to deal and that no useful purpose was likely to be served by such a conference as had been proposed

PROFESSORS OF MEDICINE AND PRIVATE PRACTICE —The question of professors of medicine undertaking private practice has caused the authorities of the Pirogoff Society to take action as expressed in D N Schbankoff's address on the influence of private practice on the general development of the medical profession, which was delivered at the ninth session of Russian medical men in memory of N I Pirogoff He observed that "it was desirable in the interests of science of the professors, and of the patients that professors of medicine should be suitably paid and that they should under no circumstances fill up supplementary places, open private infirmaries or yet have private practices for paying patients" Considering this question to be very important, he continued "The management had addressed the following two questions to the professors of the Military Medical Academy and of the universities (*a*) Do you consider it possible, and under what conditions, to change over from the present state of the profession to such an organisation of medical aid as would safeguard the sick without it being necessary for the professors to engage in private practice? and (*b*) Do you consider private practice necessary to the professors for a general acquaintance with diseases, their course and issue in various states of society, and that the suppression of these practices would be harmful to the suffering as also to professional work and the advancement of science?'

MIDLAND MEDICAL UNION —The fourth annual meeting of this society was held at Chesterfield on Jan 26th Dr G Booth, the retiring President, was in the chair and there were also present Dr Albert Green, Mr Richard G Allen, Dr G G Macdonald, Dr W B A Smith, Dr James A Goodfellow, Mr V E Sutcliffe, Mr Flavell Edmunds Mr B J Lee Dr S Worthington, Dr W Duncan, Mr A Chawner, and the general secretary, Mr G S O'Rorke The annual report, on the proposition of Dr Macdonald seconded by Dr Smith, was adopted On the proposition of the President, seconded by Mr Edmunds, Dr Macdonald was elected to the office of President Dr Booth then vacated the chair and Dr Macdonald, the newly elected President, presided over the meeting The officers for the ensuing year were then elected as follows —Vice President Mr R G Allen Honorary treasurer Dr F R Mutch Council representing the Nottingham branch Dr A Fulton, Dr J H Thompson Mr J H Cox (honorary secretary), and Dr J W Noble (honorary secretary), representing the Mansfield branch Dr G T Tate, Dr E H Houfton, and Mr C J Palmer (honorary secretary), representing the Belper branch Mr R G Allen, Dr G G Macdonald, and Dr W B A Smith (honorary secretary), representing the Chesterfield branch Dr J G Shea, Dr G Booth and Dr W Duncan (honorary secretary) Honorary auditors Mr J H Cox and Dr A Fulton General secretary Mr G S O'Rorke On the proposition of Dr Smith, seconded by Dr Booth, Dr G Brittan Gill of Belper was elected a member of the union Dr Smith proposed, and Dr Booth seconded, that a list of the members of the union should be added to the report The proposition was carried and the general secretary was instructed to add the list accordingly It was resolved that the annual dinner should be held on Thursday, March 9th, and that the arrangements for the same should be left in the hands of Dr Booth, Dr Worthington, and Dr Shea as a subcommittee

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

BOWMAN, L., M.B., C.M. Edin., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Cardenden District of the county of Fife.

BURNETT, ARTHUR H., M.R.C.S. Eng., L.R.C.P. Lond., has been appointed House Surgeon to the Rochdale Infirmary.

BYERS, J. W., M.D. R.U.I., has been reappointed Examiner in the Department of Midwifery in the Royal University of Ireland.

CROSLAND, G. W. [illegible] Honorary Sur[illegible]

PEARSON, J. SIDN[illegible] appointed Casualty Officer and House Surgeon to the Victoria Hospital for Children, Chelsea.

ROWELL, J. GEORGE, M.R.C.S., L.R.C.P. Lond., has been appointed Honorary Surgeon to the Huddersfield Infirmary.

SCOTT, GRAHAM, M.R.C.S., L.R.C.P. Lond., has been appointed Junior Anæsthetist to the Central London Throat and Ear Hospital.

SHANNON, DAVID, M.B., Ch.B., has been appointed Clinical Assistant to the Chelsea Hospital for Women.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

AYLESBURY, ROYAL BUCKINGHAMSHIRE HOSPITAL.—House Surgeon, unmarried. Salary £100 per annum, rising to £120, with board and apartments.

BETHNAL GREEN INFIRMARY AND WORKHOUSE.—Assistant Medical Officer. Salary £100 per annum, with apartments, board, and washing.

BIRKENHEAD AND WIRRAL CHILDREN'S HOSPITAL, *Woodchurch-road*, Birkenhead.—House Surgeon. Honorarium £100, with board, residence, and laundry.

BIRMINGHAM GENERAL HOSPITAL.—Resident Medical Officer. Salary £70 per annum, with residence, board, and washing.

BRISTOL ROYAL INFIRMARY.—Resident Casualty Officer for six months. Salary at rate of £50 per annum, with board, lodging, and washing.

CANCER HOSPITAL, Fulham-road, London, S.W.—Assistant House Surgeon for six months, renewable. Salary £70 per annum, with board and residence.

CENTRAL MIDWIVES BOARD, 6, Suffolk-street, Pall Mall, S.W.—Registered Medical Woman as Inspector.

CHELTENHAM GENERAL HOSPITAL.—Junior House Surgeon, unmarried. Salary £50 per annum, with board, lodging, and washing. Also Surgeon-in-Charge of the Branch Dispensary, unmarried. Salary £90 per annum, with board, lodging, and washing.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria-park, E.—Two House Physicians for six months. Salary at rate of £30 per annum, with board and residence. Also Physician to Out-patients.

COLCHESTER, EASTERN COUNTIES' ASYLUM FOR IDIOTS, IMBECILES, AND THE FEEBLE-MINDED.—Resident Medical Attendant, unmarried. Salary £125 per annum, with apartments, board, and washing.

EGYPTIAN GOVERNMENT (MINISTRY OF PUBLIC INSTRUCTION).—Professor of Pathology and Bacteriology at the School of Medicine, Cairo. Salary £800 per annum.

GUY'S HOSPITAL.—Five Open Scholarships, three (£150, £60, and £50) in Science and two (£100 and £50) in Arts.

HARTLEPOOLS HOSPITAL.—House Surgeon. Salary £100 per annum, with board, washing, and lodging.

HARTSHILL, STOKE-UPON-TRENT, NORTH STAFFORDSHIRE INFIRMARY AND EYE HOSPITAL.—Assistant House Surgeon for six months. Honorarium of £25, with board, apartments, and washing.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—Assistant Resident Medical Officer. Salary £100 per annum, with board and residence.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, London, W.C.—House Physician, unmarried, for six months. Salary £20, with board and residence.

KENT AND CANTERBURY HOSPITAL.—House Surgeon, unmarried. Salary £90 a year, with board and lodging.

KING'S COLLEGE (UNIVERSITY OF LONDON).—Professor of Anatomy, Professor of Zoology, and Assistant Physician or Assistant Surgeon for Diseases of the Throat.

LIVERPOOL STANLEY HOSPITAL.—Junior House Surgeon. Salary £70 per annum, with board, residence, &c.

MACCLESFIELD GENERAL INFIRMARY.—Junior House Surgeon. Salary £50 per annum, with board and residence.

MANCHESTER, MONSALL FEVER HOSPITAL.—Fourth Medical Assistant. Salary £100 per annum, with board, lodgings, and washing.

MEDICAL DEPARTMENT OF THE NAVY, 18, Victoria-street, London, S.W.—Three Dental Surgeons. Salary £1 per diem.

METROPOLITAN ASYLUMS BOARD ASYLUM AT TOOTING BEC.—Second Assistant Medical Officer, unmarried. Salary £120 per annum, rising to £200, with rations, lodging, attendance, and washing.

NEW HOSPITAL FOR WOMEN.—Clinical Assistants.

NORTH-EASTERN HOSPITAL FOR CHILDREN, Hackney-road, Bethnal Green, E.—Pathologist and Bacteriologist. Salary £50 per annum, with lunch.

PLYMOUTH, SOUTH DEVON AND EAST CORNWALL HOSPITAL.—House Surgeon. Salary £100, with board, residence, and washing.

ROYAL LONDON OPHTHALMIC HOSPITAL, City-road, E.C.—Curator and Librarian. Salary £120 a year.

ST. MARYLEBONE GENERAL DISPENSARY, 77, Welbeck-street, Cavendish-square.—Honorary Physician.

[illegible] nrietta-street, Covent-garden, [illegible] nonths. Salary at rate of £50 [illegible] ing.

SHEFFIELD, EAST-END BRANCH OF THE CHILDREN'S HOSPITAL.—House Surgeon. Salary £70 per annum, with board, lodging, and washing.

SOCIETY OF APOTHECARIES OF LONDON.—Gillson Scholarship in Pathology. Value £90.

WESTMINSTER GENERAL DISPENSARY.—Honorary Surgeon.

YORKSHIRE INEBRIATES' REFORMATORY, Cattal, near York.—Medical Superintendent. Salary £250 per annum, with residence, rations, coal, light, and washing.

Births, Marriages, and Deaths.

BIRTHS.

CAMERON YOUNG.—On Feb. 3rd, at Cauldwell Hall-road, Ipswich, the wife of A. Cameron Young, M.R.C.S., of a daughter.

HAYWARD.—On Feb. 2nd, at The Grange, Wimbledon, the wife of John Arthur Hayward, M.D., F.R.C.S., of a son.

LIGHT.—On Feb. 1st, at Wilton-place, Belgrave-square, S.W., the wife of Edwin Mellor Light, M.A., M.D. Cantab., of a son.

PARAMORE.—On Feb. 2nd, at Judd-street, W.C., the wife of Horace Paramore, M.B. Lond., M.R.C.S. Eng., of a daughter.

MARRIAGE.

PARK—GRIFFITH.—On Feb. 1st, at St. Edward's Church, Knighton, by the Rev. J. P. Griffith, uncle of the bride, assisted by the Rev. J. F. Fixsen, vicar of Bucknell, and the Rev. M. Lutener (vicar), William Norris Park, M.B., of Wylcwm House, Knighton, and Ardloch, N.B., to Stella, daughter of Dr. W. H. Griffith, of Whitehall, Knighton, and late of Hinckley.

DEATHS.

HARLOCK.—On Feb. 6th, at Summersdale Lodge, Chichester, of pneumonia, Harry Harlock, M.R.C.S., L.R.C.P., aged 44 years.

WELBURN.—On Feb. 6th, at Wardington Vicarage, Banbury, Charles Matthew Welburn, M.R.C.S., L.R.C.P. Lond., aged 39.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE NECESSITY TO ANSWER A MEDICAL CALL.

ON Jan. 7th an inquest was held at the Pear Tree Inn, Woolston, by Mr. B. Hartfield, the county coroner, on the body of George Golding, who had died on Jan. 6th without medical attendance. Evidence showed that about 3.30 A.M. on Jan. 6th the deceased's daughter-in-law went into his room and, thinking that he was ill, went for Mr O. T. Stephenson. According to her evidence Mr. Stephenson refused to attend unless he was first paid his fee or was given an order from the relieving officer. Mr. A. A. Rogers, who was called to see the deceased after his death, gave evidence that death was due to heart failure accelerated by chronic bronchitis and alcohol. The foreman of the jury asked Mr. P. B. Hayward, a guardian who was present in court, whether the board of guardians could not relax the rule for their medical officers to attend urgent cases without waiting for an order. Mr. Hayward replied that there was nothing to prevent a medical officer attending an urgent order. The jury returned a verdict in accordance with the medical evidence and requested the coroner to bring the case before the South Stoneham board of guardians. The case accordingly came before the guardians on Jan. 17th, when Mr. Hayward is reported to have stated that he could not help thinking that the poor were suffering from the way in which the board treated Mr. Stephenson some time ago in relation to his application for an increase of salary. Previously to that there was no trouble with regard to his attending cases an[illegible] Stephenson declined to go [illegible]n get an order from the [illegible]" Mr. Stephenson, added Mr. Hayward, was no doubt within his legal rights in acting as he did. The matter was finally referred to a meeting of the full board. At this meeting, which was held on Jan. 31st, the matter came up again. Mr. Stephenson, who was present, read a statement in which he denied that any appeals were made to him as parish medical officer and he maintained that the man came as a private patient. He had been out for the four previous nights and was very tired. Mr. Hayward, however, urged that Mr. Stephenson had no excuse as to the four previous nights, as he told deceased's son that if he could get a parish order he would attend at once This was a case of distress and one which the Poor law was intended to meet. If such cases were not to be attended to what was the use of their appointing a medical officer? He proposed:

> That the board inform Dr. Stephenson that they regret he did not under the circumstances attend this case and get the parish order afterwards [illegible]

This motion was put and carried by 16 to 4 and it was resolved that the decision of the board should be conveyed to Mr. Stephenson in writing by the clerk. From the evidence before us the case would seem entirely to turn upon whether Mr. Stephenson considered that the deceased was a private patient or a parish patient. Mr. Stephenson himself said that he never said anything about an order from the relieving officer. Deceased's son, however, said that Mr. Stephenson did say that he would go *if* a relieving officer's order was provided. Mr. Hayward, however, seems to have the not uncommon opinion among guardians of the poor who are not medical men that a parish medical officer is bound to attend anybody who comes, whether an order is supplied or not. The majority of the board, however, were not of this opinion and it cannot be too widely known that a parish medical officer is not at the beck and call of anybody who may choose to send for him. We do not suppose that Mr. [illegible]ybody [illegible] bread [illegible]edical officer is a human being and may be allowed three nights in bed per week. We should advise Mr. Stephenson to bring the whole matter before the Local Government Board as, legally speaking, the deceased being a private patient, the board of guardians had no jurisdiction whatever in the case. It had no right to censure Mr. Stephenson in the way in which it did.

PRESCRIBING AT RANDOM.

THE Potters' Insurance Company, Limited, was established a few years ago by the principal manufacturers in the Staffordshire potteries and elsewhere and one of the main objects of the company was to deal voluntarily with adult male workers in lead processes in a somewhat similar way to that in which women and young persons are dealt with under the Factory and Workshops Acts. For example, arrangements were made for the periodical examination by the certifying factory surgeon of men employed in lead processes, and it may be incidentally stated that the fees paid to the certifying surgeons were on a higher scale than those to which they were entitled for a similar service in connexion with women and young persons, though within the past few months the Home Secretary has increased the latter scale approximately to that of the insurance company. Since March, 1904, this periodical examination of men has been made compulsory and now all workers in lead processes in earthenware and china factories must be examined by a certifying surgeon once a month. Another admirable piece of work was the distribution by the company of large placards to be placed in the workplaces of the workpeople concerned. These placards point out the necessity of paying constant attention to personal cleanliness, especially as regards the hands, finger-nails, and teeth, and urged the importance of making as little dust as possible and of washing out the mouth before each meal. With such a creditable record and with such an evident desire to combat the ill-effects of [illegible] should ha[illegible] letter to [illegible] ware and china factories The letter is addressed from Tunstall, Staffs., is signed by the secretary of the insurance company, and *reads* —

> DEAR SIR,—I send you herewith samples of two kinds of mouth wash which are strongly recommended by one of the certifying surgeons of this district for use by persons engaged in lead processes. Arrangements are being made for the sale of the preparations in your district and I shall be glad if you will kindly urge the use of one of them upon the lead-workers coming under your examination—of course, after satisfying yourself of its efficiency.

Then follows the price of the mouth wash. The labels on the bottles containing the preparations bear the names of druggists in Longton but do not in any way indicate the constituents. It is hardly to be expected that even the "strong recommendation" of an anonymous certifying surgeon will suffice to induce his colleagues to advise the use of a mouth wash of which they do not know the composition. They are quite capable of prescribing a mouth wash when one is necessary. One mouth wash contained, according to our analysis, wintergreen, glycerine, alcohol, boric acid, and salicylic acid. In the other carbolic acid appeared to be the chief constituent in association with a foaming agent.

ASEPTIC FURNITURE.

To the Editors of THE LANCET.

SIRS,—In reply to the letter published on p. 334 of THE LANCET of Feb. 4th we beg leave to state that we made up our pattern of aseptic table from the suggestions and at the special request of some leading surgeons who had seen other patterns of aseptic tables and had found certain defects and imperfections in them. These defects were laid before us and after many experiments and much consideration our present registered table was produced and it differs in important details of construction from any other on the market.

With regard to the new St Mary's Hospital, Manchester, we fitted up not only one of the operation theatres but also a considerable part of the out-patients' department, sterilising room, wards, &c., of the hospital referred to with our improved aseptic table as well as other furniture made of phosphor bronze.

We are, Sirs, yours faithfully,
For Allen and Hanbury, Ltd.,
HENRY LEWIS, Manager

Wigmore street, London, W., Feb 6th, 1905

"SUNSHINE IN GUERNSEY."

IN a letter under the above heading which appeared in our issue of Feb 4th, p. 322, Dr H D Bishop referred to Hastings with 1715 hours of sunshine in 1904 as "the sunniest town in England for that year." A correspondent now writes to us to say that from the municipal meteorological records of Ramsgate it appears that in 1904 that town was blessed with 1726 hours of sunshine.

"WHAT APPENDICITIS IS."

A CORRESPONDENT has forwarded us a cutting from the *Newcastle* [illegible]

> [illegible] operation has been performed whether the case is appendicitis or inflammation of the kidney itself. The little appendage to the [illegible] appendix.
>
> The operation consists in making an incision through a line down to the kidney, relieving matter and pus, if such were found outside the kidney, and finally extending the wound or extending part of the wound to the kidney itself, to ascertain if there be any stone in the kidney which might be found to be the cause of the inflammation. The operation occupies about half an hour.

We seem to remember that the same eminent physician published the same remarkable tissue of misstatements about the time that His Majesty the King was suffering from appendicitis in the year 1902. [illegible] Bourbo[illegible] forget [illegible]

"The Eternal City" suggested nephrectomy as a suitable operation in a case of cancer of the breast but then he is not an eminent physician. It is a pity that responsible organs of public opinion should publish statements upon purely professional matters without previously verifying the truth or falsehood of such.

A DISCLAIMER.

To the Editors of The Lancet.

Sirs,—I herewith inclose a cutting of a notice appearing in yesterday's issue of our local paper without my knowledge and consent. I immediately wrote to the editor of the paper asking him to insert in his next issue my letter in which I entirely deny any knowledge of the matter. I will forward a cutting from next week's issue.

I am, Sirs, yours faithfully,
Arthur H. Turner, L.S.A. Lond., M.O.H., &c.
Beaconsfield, Feb. 4th, 1905.

*** The notice, to which our attention has already been called, is an advertisement expressing the thanks of a patient to Mr. Turner.—Ed. L.

PHOTOGRAPHY AND HEALTH.

Now that the bright days are coming on and the amateur photographer is thinking about furbishing up the fittings of his cameras and their accessories and hunting about the house for stray developing dishes, trays, tweezers, printing frames, toning solutions, and photographic sundries (not to mention his surreptitious survey of the culinary department and the cook's dishes), we think it will not be out of place to sound a note of warning in regard to his ruby lamp and its connexion with his health. Many a young amateur photographer spends hours down a dark and dingy cellar in the spring-time and summer developing dry plates which may turn out to be negatives or negative quantities and all the while he is holding his nose over a smoking oil lamp emitting an offensive smell. An hour or so of this gives him a headache and he staggers up the stairs and perhaps feels queer for the rest of the day. Very often, with his eyes strained and rivetted on the plate which he is rocking in its earthenware bath, he is perfectly oblivious of the smoking lamp and even when he awakes to realise it perhaps the handle of the lamp is inside and he dare not open the lamp and expose his half-developed plate to the yellow light of the naked flame for fear of "fogging" it. The amateur photographer who uses ruby or other lanterns should buy those having handles to regulate the wick which are accessible from the outside of the lantern and should employ only the best oil. Further, he should see that his dark-room or "den" is properly ventilated while still being light-tight. Some use candles but often they gutter and flare and go out at awkward moments. A better way is to use a gas lantern which can be regulated to a nicety but the best of all ruby lights is perhaps an incandescent electric lamp with ruby glass—the glass, however, must be of a ruby of a deep rich red, as it is difficult to regulate the amount of light emitted by an ordinary incandescent electric lamp.

THE HYGIENE OF THE BARBER.

On Sept. 24th last there appeared a leading article in The Lancet with the above title and we are now glad to congratulate Dr. W. Collingridge on the evident spread of hygiene among barbers in the suburbs of London. In the Romford-road we notice that a barber has opened a shop—evidently the proprietor has been converted by Dr. Collingridge—as "The Antisceptic Shaving Saloon."

THE CASE OF DR. A. D. GRIFFITHS.

To the Editors of The Lancet.

Sirs,—May I be allowed to trespass still further on your space to announce the following further contributions to the above fund?—

	£	s.	d.		£	s.	d.
Amount previously acknowledged	30	18	6	Dr. Hastings Torney ...	0	10	6
Deputy-Inspector-General L. H. Kellett	0	10	0	Dr. T. D. Griffiths	2	2	0
Mr. W. C. Humphreys ...	1	1	0	Mr. Evan Jones	0	10	6
				J. D. M.	0	10	6

"COMMENDADOR PORT WINE."

In an analytical notice of this wine in The Lancet of Dec. 24th, 1904, p. 1791, the figures given for the alcoholic strength were (by an oversight) not corrected for temperature. Corrected for normal temperature (viz., 60° F.) they should read as follows: Alcohol, by weight 18·54 per cent., by volume 22·73 per cent., equal to proof spirit 39·84 per cent.

◆

Dr. T. Carter Booth.—The increase of carbonic acid gas (as an index of impurity) could readily be ascertained by means of Lunge and Zeckendorf's simple apparatus (to be obtained from Messrs Baird and Tatlock, Hatton-garden, London, E.C.) Again, it would appear from a note in The Lancet of Jan. 21st, 1905 p. 195, that small quantities of carbon *monoxide in the air may* easily be *determined* by passing the air through a U-tube containing periodic acid at 80° C. In the presence of carbon monoxide iodine is liberated which may be intercepted by chloroform and the amount estimated by the depth of colour produced.

T. E. L.—We do not suppose that the practitioner mentioned in the cutting which our correspondent inclosed is in any way responsible for the appearance of the paragraph.

Inquirer V.—An analysis of vibrona was published in The Lancet of Feb. 26th, 1898, p. 582. The basis of the preparation was hydrobromate of cinchona.

M.R.C.S.—Our correspondent will find our opinion on the matter set out in a leading article on p. 412 of The Lancet of August 17th, 1895.

E. A. P.—The preparation contains 8 per cent. of citric acid with colouring matter and glycerine.

Yanatas.—The bottle sent contained potassium bromide, chloral, and a pungent principle resembling capsicin.

Erratum.—An eagle-eyed correspondent writing from Canada informs us that on p. 30 of The Lancet of Jan. 7th the name "Herder" should be *Herter.* We are much obliged to our correspondent for his correction which is certainly right.

Communications not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (13th).—London (2 p.m.), St. Bartholomew's (1.30 p.m.), St. Thomas's (3.30 p.m.), St. George's (2 p.m.), St. Mary's (2.30 p.m.), Middlesex (1.30 p.m.), Westminster (2 p.m.), Chelsea (2 p.m.), Samaritan (Gynæcological, by Physicians, 2 p.m.), Soho-square (2 p.m.), Royal Orthopædic (2 p.m.), City Orthopædic (4 p.m.), Gt. NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen-square, Bloomsbury, W.C.).—3.30 P.M. Dr. Ferrier: Cerebral Tumours.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. II. of 1904, which was completed with the issue of Dec. 31st, and the Title-page to the Volume, were given in THE LANCET of Jan. 7th.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1904 are now ready. Bound in cloth, gilt lettered, price 18*s.* carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

Clinical Lecture

ON

A CASE OF GANGRENOUS APPENDICITIS, WITH SUBPHRENIC ABSCESS.

Delivered at Guy's Hospital

BY CHARTERS J. SYMONDS, M.S. LOND., F.R.C.S. ENG.,
SURGEON TO GUY'S HOSPITAL; EXAMINER IN SURGERY AT THE UNIVERSITY OF LONDON.

GENTLEMEN,—No apology is needed for bringing this subject before you to-day in view of the uncertainty prevailing in the minds of many as to the moment for operation and also in view of the increased frequency of the malady. The case forming the subject of this lecture was one of three operated upon on the same day, all being acute cases. My remarks will be limited to the acute forms of appendicitis, cases which die early, cases where operation must be performed within three days and sometimes within 24 hours. It is impossible within the scope of one lecture to deal adequately with this branch of the subject and the remarks will therefore be confined to the points raised by a single case.

The patient, a girl, 16 years of age, on Thursday, Feb. 4th, did not feel very well but being anxious to go to a party made no complaint. During the evening she had abdominal pain and on returning home this was severe. She spent a restless night and there was much pain but she did not call for assistance. On the next day, Friday, the pain continued and she was frequently sick. As the menstrual period began on this day less importance was attached to the symptoms by the girl's mother. On Saturday, the 6th, medical advice was sought. The girl on the morning of this day was found with great pain in the right iliac region. The temperature was 101° F. and the pulse was 104. As the pain was less a sedative was not administered. All day she remained ill and in pain. In the evening the temperature was 104°, the pulse was 120, and I was telephoned to for advice as her medical attendant considered the symptoms severe. In this view I concurred and added that if the temperature kept up and the pain continued for 12 hours an operation ought to be performed at once. Next morning (Sunday) the temperature was 104°, the pulse was 120, and the pain was still severe. At 5 P.M. on this day—the third of the illness—I saw the patient. She showed marked general irritation, in a flushed face, a distressed look, a restless manner, a temperature of 104°, and a pulse of 120. So it may be taken that the temperature had been at this level continuously for over 24 hours. There had been no sickness during the day but she had taken very little food. The right iliac region was extremely tender and here a definite swelling could be felt, but the tenderness was too great for accurate examination. There was no general distension of the abdomen and as there had been no rigor there was less fear of metastatic deposits having already occurred.

The question of operation had to be decided and, moreover, a prognosis given as to the result that would attend such an undertaking. The following points were raised as indicating the wisdom of immediate operation:—The onset of the case had not been sudden—i.e., the girl had not been seized with sudden alarming pain, as we commonly see both in severe cases and in many cases where the attack is short and carries little risk. It will be noticed that the patient felt ill on Thursday but was able to conceal her distress [illegible] Gradually the pain increased [illegible] Probabl [illegible] been fou [illegible]

This form of onset indicates a septic inflam [illegible] wall of the appendix, a process that precedes [illegible] often painless and, so far as my experience goes, [illegible] grave issue. I mean to convey that an onset of this kind, if followed by a continuous temperature and especially if followed in 24 or 48 hours by acute pain, always demands early operation. This is the type also that leads to septic absorption with metastatic abscess in the liver or in the lung, or again to subdiaphragmatic abscess.

As an illustration of the importance of this period antecedent to the attack proper, let me refer to the case of a man, about 40 years of age. On Thursday he felt, as he said, "seedy" and paid a casual visit to a medical friend, not his usual attendant. On the next day he took a pill and was not quite up to his duties. During the night—to be more accurate about 4 A.M. on Saturday—he was seized with severe abdominal pain and when seen an hour later he was in a state of collapse. His medical adviser very properly gave a full hypodermic dose of morphine and went home to prepare for immediate operation. When next seen the patient was so comfortable that interference was postponed. The delay was fatal, for the patient died three days later without developing any [illegible] last few hours. Had the full va[illegible] been app[illegible] success [illegible] attack of [illegible] fore due [illegible] or even perforation, the [illegible] with careful watching would have been justifie[illegible] case—i.e., on one where [illegible] indefinite illness given [illegible] immediate operation.

What does this early stage indicate? If carefully observed it will be found to be one of pyrexi[illegible], the severity depending upon the virulence of the poison. [illegible] complained of headache and her [illegible] was looking "out of sor[illegible]." [illegible] found it to be 103° F. [illegible] child was subject to st[illegible] temperature. Next day t[illegible] and in the evening stood at 102°, and the child had indefinite stomach-ache. A medical man was sent for next morning, and though there was a suspicion of localised tenderness it was not sufficient to justify a complete diagnosis. Next day, however, the diagnosis was clear. When called to this case the temperature had been raised four days, never falling to normal, and not showing the usual excursions of the mild or hectic type. The swelling was localised and the general condition was good. Still, as the pyrexia indicated a progressive septic process in the appendix itself, carrying with it not only the danger of rapid extension of local suppuration but also of septic absorption, operation was advised. A large abscess extending to the pelvis was evacuated, a gangrenous appendix was removed, and though the septic condition retarded recovery a few days it was complete and rapid. This case occurred some six years ago.

I want to impress upon you by the introduction of these [illegible] of the period preceding an acute onset or [illegible] arly observation of the [illegible] ave us nearly two days' [illegible] on on apparently the [illegible] ten quoted this case to justify the household use of the thermometer, for its employment by mothers is more often laughed at than commended. I want you to learn that the stage of malaise is a pyrexial one, that when acute pain follows, as it did in the man, immediate operation is demanded, even when we have the patient's history alone as a guide. The case of the child will show you that a septic process has been in operation and we learn that sudden pain or rapid advance of local signs means perforation or rapid extension, not early distension or kinking. The second point was the continuously elevated temperature. We must note that it was not a question of a morning fall and an evening rise nor of marked excursions, but the temperature early rose to 104° and remained more or less at this level for over 24 hours. When this sign persists on the third or the fourth day it indicates a gangrenous infection of the appendix and, I believe, always demands operation. The great danger in such a condition is that of septic absorption, which exists all the time the tem[illegible] Remember, the great and fundamental [illegible] *to normal and remains there* [illegible] *appendix has ceased, provided* [illegible] *elsewhere.* Also remember, [illegible] *l temperature the abscess may nevertheless be extending in the peritoneum. Even if the pus be very foul, the peritoneum does not absorb the septic poison.* I do not wish to convey to you the notion that temperature is the main sign of danger. When you stand beside these cases you will recognise the symptoms always associated with septic poisoning, symptoms of as great value as the pyrexia itself. It is more difficult to make friends see the importance of the restless state, the loss of appetite, the flushed face, the irritable and rapid pulse. Often the patient is said to be nervous, excited, and the general signs are belittled. Then a high temperature is convincing to friends and is of the greatest service, as a lever, in moving away objections.

These, then, were the three main grounds for advising immediate operation—viz., the prodromal stage followed by a rapid development of symptoms, the continuous high temperature, and the accompanying signs of septic poisoning. One great and serious doubt remained. Had a metastatic deposit already formed, possibly rendering operation useless? There were no physical signs of pneumonia; one of the most common complications but happily a recoverable one; nor was there any general abdominal distension. The question of hepatic infection one could not so easily exclude, for it is well known that in the early stages this infection gives few localising symptoms. As it is always a fatal complication operation on the appendix gives only temporary relief.

These then were the questions be[illegible] tion. To my mind the necessity for [illegible] obvious and no objection was raised. [illegible] be content with opening and draining an abscess in such cases. The appendix must be removed to prevent further septic absorption. The choice of method was of some interest. The case having been seen early—viz., the end of the third day—the amount of pus being probably small, and as, moreover, the swelling was in the most accessible position, I elected to split the muscles as giving the strongest abdominal wall and also in the circumstances a sufficient opening. I have in the wards pointed out to you the obvious objections to dividing the abdominal muscles where pus is present and have advocated in all acute cases where possible the muscle-splitting operation. In cases where the appendix occupies an unusual position, e.g., in the pelvis or the loin, or in relapsing cases where also extensive adhesions are expected, then we must enter through the rectus sheath to obtain unlimited space. As the swelling in this case was close to the iliac spine the muscles were split and foul pus was evacuated at once, the general peritoneum as yet being unopened. Carefully all pus was mopped away with plain gauze boiled with the instruments and with dry cyanide gauze. Then the appendix was separated from the iliac fossa and the route to the pelvis was opened. Down into the pelvis was pushed a long strip of plain gauze which had been boiled just beforehand. Another piece was passed under the anterior abdominal wall and a third into the loin, all three pieces being held in forceps. Then the appendix was drawn out and its mesentery was ligatured and divided. The appendix was ligatured close to the cæcum without any preliminary turning down of a cuff or subsequent burying of the stump. Again the cavity left was carefully cleansed with gauze pads. Then the pelvic strip was withdrawn and was found to be soaked with blood-stained fluid. This could not have arisen during the operation as no fluid was introduced and was no doubt serum derived from the infected peritoneum. In a few hours this would have become foul pus. Several times the pelvis was dry mopped. Then the other two gauze strips were removed and were found to be clean. To exclude accumulations in other localities a pad was passed well into the right loin and another over into the left iliac fossa without [illegible] or pus.

You will notice, plea[illegible] not employed. On another occasion I will bring forward evidence to show that it is unnecessary and I believe also adds additional dangers in all cases, especially in the form now under consideration. A drain made of a large rubber tube surrounded with a thick layer of cyanide gauze was passed down to the bottom of the pelvis and a salmon-gut suture was inserted in either end of the skin incision. Let me delay for one moment over this method of draining. It has the advantage of shutting off the peritoneal cavity and of allowing the escape of serum. Gauze is essential in draining all these intra-abdominal abscesses as it promotes rapid adhesion. An uncovered rubber or glass tube does not do this and even where the peritoneum has apparently not been opened a small crack may have extended through the inflammatory material. Extension may occur through this unnoticed crack when a rubber tube only has been used but the gauze will prevent it. The only other method of using the gauze, and one giving even greater certainty and to be employed when there has not been sufficient time to clean the cavity effectually is to pack in first a broad web of gauze and to fill up the cavity thus formed with strips. I now when using this method place the gauze-covered rubber tube in the centre and then fill with gauze round it. Finally, this gauze should be wrung out of a strong antiseptic—1 in 20 carbolic or a 2 per cent. lysol, &c. The usual gauze dressing was applied, and the patient was put into bed.

We had reason to be well satisfied with our work and especially was it my duty to congratulate my medical friends [illegible] e patient so early to operation and upon [illegible] and thus allowing me to see the worst aspect of the case. Too often is one called late because of the fear that operation increases the danger. Gentlemen, I hope to show you in this or the next lecture that operation should add little or no danger apart from the general risks. In leaving the case I was obliged, however, from a fairly large experience of these cases to say that though no evidence existed at the moment, yet the possibility of a septic deposit already having formed in or about the liver could not be excluded. Had there been no ingravescent [illegible] ontinuous elevation of the temperature, and had [illegible] of acute general poisoning been absent, [illegible] not have left this one cloud behind. On the next day the temperature was 100°, the pulse was 80, and all looked well. Then signs of general irritation returned, the liver was observed to be lower than normal, and on examining the base of the lung signs of pneumonia were noticed. The breathing was not laboured, nor was there any pain or cough. The temperature again rose and when I inquired on the Friday, the fifth day from the operation, it was 103°, the pulse had risen, and the basal signs were more marked. The operation wound was reported to be doing well. As described through the telephone, these signs indicated the existence of a secondary infection in one of three situations—in the lung, in the liver, or in the peritoneum under the diaphragm. The pulmonary infection is nearly always in small areas and often multiple and not basal. Sometimes the clinical examination reveals very little. Though I have had several cases recover with marked pulmonary infection, in none has there been typical basic pneumonia. This is indeed the usual experience. The occurrence of marked jaundice on the second day after the operation was in favour of hepatic abscess. This is not the place to discuss the early signs of this complication. The subject has been well treated in our Reports recently by Dr. J. H. Bryant and some years ago by Dr. R. E. Carrington. As described to me the case sounded more like a subphrenic abscess. The liver was depressed—or was it swollen from perityphlitis? The pulmonary signs indicated lung pressure and œdema from a neighbouring infective centre. Suspecting fluid a needle had been twice inserted, on one occasion removing a few drops of serum.

All this information was obtained by telephone, the patient living in the country. My answer was that a subphrenic abscess probably existed, that it was invading the diaphragm, had already given rise to pulmonary œdema, and that we must interfere at once or it would rupture into the pleura or the lung. I arranged to go early next morning. On arrival at 8.30 on Saturday (Feb. 20th) I was met with the remark, "The girl is very bad: she has been coughing up foul pus since 5 o'clock." The event predicted had occurred. Was the pus thin and pale or was it blood-stained and chocolate in colour? The first would mean a subphrenic abscess and a hopeful outlook; the second a hepatic abscess, in which operation could only relieve and retard the fatal result. I found the patient in the greatest distress, with a flushed face, rapid breathing, and great pain in the side. The breath wa[illegible] and she was constantly expectorating [illegible] clear that a subphrenic abscess had perforated into the lung and opened a good-sized bronchus. The pleura had been sealed off, for lung sounds could be heard down to the base.

There were no time and no necessity for prolonged clinical examination, except to localise the abscess and to ascertain the best position for incision. Chloroform was administered and the subphrenic region was explored from *behind* with an aspirator. Three punctures gave no results. Then percussion in front gave a resonant note, with a characteristic dead vibration as of a cavity with an opening, and here pus was found. By this time the girl's condition was much worse. Some 20 minutes had elapsed since she began the inhalation and gradually her colour was becoming more

The Hunterian Oration.

Delivered before the Royal College of Surgeons of England on Feb. 14th, 1905,

BY JOHN TWEEDY, F.R.C.S. ENG.,

PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

MR. VICE-PRESIDENTS AND GENTLEMEN,—Before undertaking the duty to which I have been specially appointed to-day, I desire to express our sense of bereavement in the loss of Mr. Luther Holden who died eight days ago in his ninetieth year. Twenty-four years ago Mr. Holden stood in this place to deliver the Hunterian Oration and those who were present will recall the gentle and genial spirit which pervaded his speech and its learning and eloquence. Within seven months this College has lost three of its past Presidents, John Birkett, John Simon, and Luther Holden, each being in turn Senior Fellow of the College. Great and varied as were the abilities and attainments of these distinguished men, and different as were the manifestations of their intellectual and professional activity, they had at least one great quality in common. Called upon to occupy exalted positions in the surgical profession and elected to the highest office in this College they, each and all, in an age of wealth and luxury, lived simple and unostentatious lives, careful only for the faithful discharge of their various duties. In this way they set a worthy example to their professional brethren and in the nineteenth century maintained the high ideal embodied in the Hippocratic oath—"In purity and in righteousness I will pass my life and practise my Art."

Hunter, the anniversary of whose birth we celebrate to-day, did not leave behind him a systematic collection of medical and surgical writings such as the first four writers I have named, nor did he make any capital discovery, such as Harvey's, respecting the circulation of the blood; but the influence which he exercised upon biology and upon surgery was perhaps more immediate and more penetrating than that of any of his predecessors and it has been more continuous and more progressive.

Harvey's discovery was *sui generis* and well deserves the eloquent characterisation of Haeser as "the most brilliant triumph of experimental physiology." In all essential respects it was definitive and final. "A demonstrated truth," says Aristotle, "is an eternal truth," and such was Harvey's. It changed the conceptions of physiologists and physicians as completely as Kopernik's heliocentric theory changed those of astronomers; and it became the starting point of modern progress i[illegible] surgery. Thanks to the labour[illegible] completed by the discovery [illegible] Malpighi and the discovery of the chyliferous vessels by Aselli and Pecquet, physicians and philosophers were enabled to look upon man and his organism, upon structure and function, upon nutrition and growth, and upon the problems of health and of disease from a new point of view.

Throughout the ages of civilisation the growth of knowledge has been slow and often irregular, but it has been continuous and it has been sure. How slow and yet how sure we may realise by comparing the dialectic notions of Aristotle respecting weight and motion with the direct appeals to the evidences of the senses afforded by the demonstrations of Galilei, whereby it was shown that so far from there being in nature bodies possessing positive levity, all matter is equally affected by gravity, irrespective of its form, magnitude, or texture. By the simple experiment of dropping objects from the Tower of Pisa, Galilei, who began life as a medical student, laid the foundation of modern physical science and especially of dynamics. This expedient was one of the first appeals, at least in modern times, to the use of direct experiment in physical science and the truth thereby established became a determining factor in Newton's great discovery of the law of gravitation. From Aristotle to Galilei an interval of more than 18 centuries had elapsed. Galilei and Harvey were contemporaries. John Hunter was born exactly a century after the publication of Harvey's *Exercitatio de Motu Cordis*. It is one hundred and eleven years since John Hunter died. Yet how modern Hunter is. Inventions and discoveries now crowd upon us so thick and fast that we are apt to forget how recently modern physical science began and especially modern medicine. In the order of time medicine, in its rudest and simplest forms, must have been one of the first of the empirical arts, but in the order of ideas it was one of the last to enter into the hierarchy of the sciences. As a system of organised knowledge medicine pre-supposes and requires not only centuries of clinical observation and a complete logical apparatus, but it also requires an advanced state of all the other natural sciences. It concerns itself with the recondite problems of life in the most complex and the most highly differentiated of its manifestations, whether under the conditions of health or under those of disease. Until physics and chemistry had advanced from the conjectural and the *aprioristic* to the scientific stage medicine could only be conjectural and *aprioristic* too, however useful it may have been as a practical art. The thoughts and labours, the experiments and discoveries of the great pioneers of modern knowledge in the physical sciences were the necessary prelude to a scientific progress in biology which in its turn was a condition precedent to any real advance in the science of medicine, surgery, and pathology. Harvey in the order of time and of thought was the necessary antecedent of Hunter.

The history of John Hunter's birth and parentage is well known. The starting point of John Hunter's career as anatomist, biologist, and surgeon was in the year 1748, when he came to London with a receptive and intelligent mind, a quick and observant eye, and a well-trained hand, to collaborate with his brother William in the anatomical school which had been started two or three years before. It has been alleged that John Hunter had little or no school education and that he was a wayward and careless youth; and it has been argued that his lack of scholastic training hampered him in after life, more particularly with reference to his powers of verbal description and exposition. I suspect, however, that the defects of Hunter's general education have been exaggerated. It is certain they had no detrimental effect upon the vigour of his intellect or upon the correctness of his methods of work. John Hunter probably knew little, perhaps he knew nothing, of formal logic or of the history of ideas or of scientific methods, but with the instinct of true genius he soon found the only path that leads to genuine knowledge and he kept it undeviatingly to the end. Contrasts have often been drawn between John Hunter and his brother William and the differences between the two men have usually been ascribed to a difference in education. This, I believe, is not the correct, and certainly it is not the only, explanation. There was a difference between the two brothers but it was a difference of temperament and disposition, a difference which was only indirectly, if at all, determined by education. Be this as it may, the differences were subdued to a great purpose. The qualities of the two brothers became complementary one of the other. The manipulative skill and the tireless research of John furnished ample materials for the display of William's splendid powers of exposition and so each in his own way contributed to the success and fame of the first and greatest school of anatomy in England.

Considering the important part that human anatomy now plays in medical education it is difficult to conceive that there was no systematic teaching of anatomy in England before the middle of the eighteenth century. During the many centuries which elapsed between, say, the time of Hippocrates and the middle of the sixteenth century the dissection of the human cadaver was almost unknown. Forbidden alike by the laws and customs and religion of the ancient Greeks and by the creed of Mohammad, the study of human anatomy was placed under a civil and religious ban until the end of the thirteenth century. In ancient Greece the laws relating to immediate burial were very stringent. Even victorious generals had been condemned to death because they neglected to bury the slain. The pathos of Sophocles's tragedy of Antigone turns, it will be remembered, upon the sacredness of the dead and of the necessity, higher than imperial commands, of immediate burial.

When the tradition of [illegible] medicine passed, in the seventh [illegible] eighth [illegible] into the [illegible] of the

No. 4251.

Mohammadans human anatomy was equally neglected, the practice of dissection being implicitly forbidden by the Qurân. Albucasis, the only surgeon of first rank in the Græco-Arabian school, writing at the end of the eleventh century, deploring the decadence of surgery, says: "The reason why there is now no dexterous operator, is this:—The medical art demands time. He who wishes to practise it ought first of all to study anatomy as it is described by Galen." Albucasis cites several instances within his own knowledge of patients dying from hæmorrhage under the hands of men who had undertaken to operate without knowing where the large blood-vessels lay or how to arrest the bleeding when these vessels were divided.

Even after the dissection of the human cadaver received the sanction of the civil authorities in Southern Europe the teaching of anatomy was cursory and occasional and merely descriptive. Mundino of Bologna in the fourteenth century, who was the first in modern times to dissect the human cadaver, seems to have dissected only two bodies. So little was known of human anatomy and so strong was the tyranny of tradition, that when Vesalius in the middle of the sixteenth century alleged that the anatomical descriptions of Galen could not be adapted to man there were not a few, in their zeal to repel the accusation that Galen had used animals in dissection, who did not hesitate to maintain that the human organisation had changed since Galen's time. In England, notwithstanding Harvey's lectures on anatomy in the first quarter of the seventeenth century, there was no organised teaching of anatomy before William Hunter's time. In this matter William Hunter has not received all the credit he deserves. He came to London in the year 1741, at a critical period in the history of English surgery. In the year 1745 the union which had existed between the Surgeons of London and the Barbers of London for over 200 years was dissolved by Act of Parliament. The surgeons were incorporated by the name of the Masters, Governors, and Commonalty of the Art and Science of Surgeons and from this incorporation our College took its rise. During the union of the two companies there had been lecturers or readers on anatomy in the Barbers-Surgeons Hall, the readers being nearly all physicians, but the teaching of anatomy seems to be for the most part only descriptive and demonstrative. Upon the formation of the new Company of Surgeons provisions were made for the teaching of anatomy but the first masters were not elected until eight years later. There seems to have been throughout the greatest difficulty in getting the stewards of anatomy to perform their duties and partly in consequence of this and partly in consequence of the difficulty of obtaining "bodies" the attempt to teach anatomy was abandoned by the Surgeons' Company.

In the winter of 1745–46 William Hunter undertook for a Society of Naval Surgeons the delivery of a series of lectures on surgery. This he did so satisfactorily that he was asked to include anatomy in his course. He accordingly advertised his first course of anatomical lectures to begin Feb. 1st, 1746, and added that "the operations of surgery, with the application of bandages," would be included in the course; and also, that "Gentlemen may have an Opportunity of learning the Art of Dissecting, during the whole Winter Season, in the same Manner as at Paris." Had William Hunter's ambition been realised he would, nearly a century and a half ago, have solved a problem in early medical education in London which is still perplexing the minds of many thoughtful persons. He desired to establish an anatomical school in London upon an extensive scale. With this object in view he offered to erect a building at the cost of £7000 for the study and teaching of anatomy, provided the Government would grant him a piece of ground to build upon. It was also his intention to give to this institution all his preparations and his books. With an unfortunate lack of sympathy which British Governments have too often manifested in their dealings with science and education William Hunter's offer was declined. Smarting under a keen sense of disappointment and full of resentment he determined to transfer his favours to Glasgow, which now enjoys the possession of his priceless museum and library. *Beati possidentes.*

William Hunter's memory deserves at least this passing tribute of our respect. He attempted to place medical education in London on a sound and permanent basis. But we of this College owe his memory a further debt of gratitude, for he was John Hunter's early patron and protector and took every occasion and opportunity to advance John's worldly interests and to promote his reputation in the surgical and the scientific worlds.

After John Hunter had worked at human anatomy for about ten years he manifested his intellectual growth by directing his thoughts to the higher and more scientific discipline of comparative anatomy and physiology. He realised that human anatomy alone was an insufficient guide to pathology and surgery. He collected all manner of animals at his house and grounds at Earl's Court in order to study their ways and habits and from every available source he acquired animals, living or dead, for the purposes of observation, experimentation, or dissection. In his use of the lower animals for the elucidation of physiological problems he followed while amplifying the practice of Harvey, who in his turn adduces the authority of Aristotle. There was, however, a striking and characteristic difference between the use which Aristotle made of the dissection of animals with reference to human anatomy and that of Hunter. There is no trustworthy evidence that Aristotle or Hippocrates or even Galen dissected the human body, certainly not in the sense we understand by the term "dissection." They dissected the bodies of animals *instead of* those of man and transferred their observations of animals to the corporeal organisation of man. Hunter, on the other hand, practised the dissection of lower animals *in addition to* that of man and transferred his observations to the embryology and morphology of man and to the elucidation of the problems of human and comparative physiology and pathology.

John Hunter was a philosopher in the strict and primary sense of the word. He had a passion for knowledge. "Let no man presume to call himself wise," says Pythagoras, "God alone is wise. Man can never get beyond the passion for wisdom." John Hunter had this passion. He devoted himself to the pursuit of knowledge, searching for it in every department of the organic world, animal and vegetable. In one of his letters to Jenner he says: "I have but one order to send you, which is, to send everything you can get, either animal, vegetable, or mineral, and the compound of the two, either animal or vegetable mineralised." And, again: "Have you any large trees of different kinds that you can make free with? If you have, I will put you upon a set of experiments with regard to the heat of vegetables." With respect to the observations and experiments which he directs Jenner to make he says, "Be as particular as you possibly can." These sentences express briefly and in epitome, as it were, Hunter's habits of mind and his attitude towards the problems of organic life.

John Hunter may have lacked the power of clear exposition and he may have disliked routine teaching. He was, however, full and overflowing with ideas, new and original, to which he often found it difficult to give distinct shape and utterance. In contrast with William Hunter's didactic powers John had the suggestive, the constructive, the creative faculty, the faculty of discovery, of coördinating knowledge, and he had the art of stimulating thought and calling forth effort from others. He taught by example rather than by precept. It is clear evidence of the value of John Hunter's method of teaching that he attracted to his classes the best students and surgeons of his day, men who afterwards rose to the highest eminence—Edward Jenner the vaccinator, Dr. Physick of Philadelphia, Abernethy, Cline, James Earle, Astley Cooper, Lynn, and Anthony Carlisle. These men in after life repeatedly expressed their indebtedness to Hunter and to his personal influence as a teacher.

What, then, did Hunter do? The ready answer comes that he made one of the largest and most instructive collections of anatomical and biological specimens known to history: his famous museum, which is now lodged within the walls of this College and which it is our pride and privilege to protect, to preserve, and, so far as may be possible, to perfect. But I venture to think that however great, notable, and precious Hunter's museum may be it represents only the material part of him. The spirit which animated him, the germinative character of his method, the impulse which he gave to the operation of mind in the pursuit of biological knowledge were infinitely greater and infinitely more precious. *That*, amid the accidents and mischances of time may pass away, but *these* will abide as long as civilisation on this earth endures. What Hunter did from the material side is sufficiently well known. His contributions to surgery and biology have been repeatedly enumerated, expounded, and eulogised in this place and elsewhere. I shall, therefore, not attempt to repeat what has been already done so often and so well but I desire rather to draw attention to Hunter s method—to consider not so much *what* he did as *how* he did it

Ottley, the first and one of the best of Hunter s biographers, remarks that in pursuing his researches Hunter strove not, like many of his more learned and less philosophical predecessors, to unravel the mysteries of Nature by taking up principles *a priori* and seeking for facts to support his theory but that, on the contrary, he followed in the strictest manner the inductive method laid down by Bacon as the only sure though arduous road to knowledge and Babington, in his Hunterian Oration, remarks of him "He had never read Bacon but his mode of studying Nature was as strictly Baconian as if he had" Other critics and historians of Hunter's work and not a few Hunterian orators have written or spoken in a similar strain In my judgment this opinion is entirely erroneous with respect to Hunter s method and it is a complete misinterpretation of the Baconian system Bacon's eloquence and influence undoubtedly did much to attract men to the study and observation of natural phenomena He called attention to the necessity of studying the powers and forces of the world as a means of subjecting the world to the human mind and so far his message was appropriate and opportune The significance of that message is probably greater now than at the time he delivered it The future belongs to the nation which understands best the forces of nature and which can most skilfully and economically employ them But Bacon himself neither knew nor understood the physical sciences His spirit was essentially mediæval and much less modern than that of his illustrious namesake Roger Bacon who lived 300 years before him Francis Bacon's aim was purely utilitarian He had no idea of knowledge for its own sake and he cherished the hope that by increasing our knowledge of nature the secret of the transmutation of substances would be learnt and probably the knowledge of the making of gold He not only had no practical acquaintance with natural science but he lacked insight into the true methods of its investigation He understood very imperfectly the value of the experimental method and assigned a subordinate position to quantitative determination the precise quality which is the most striking characteristic of modern science and which constituted the most original and perhaps most brilliant of the reasonings which Harvey employed in his famous Induction So far from being the founder of the modern scientific method Bacon s writings were themselves one of the products of the intellectual awakening which began at the end of the sixteenth century Notwithstanding his affectation of scientific knowledge and scientific methods Bacon had an unscientific weakness for superstitions He believed in natural and judicial astrology, through not without some hesitation and discrimination He believed in the transmutability of elements and of the metals in charms and signatures as remedies and so completely did he ignore Harvey s discovery of the circulation of the blood that in one of the latest of his writings he ascribes the pulsation of the heart and arteries to the dilatation and contraction of the spirits Well might Harvey say in disparagement of Bacon s scientific writings ' He writes philosophy like a Lord Chancellor '

Bacon s ruling idea was the collection of masses of facts and then the employment of processes of arrangement and separation and exclusion so artificially contrived that a man of common intelligence should be able to announce the truth sought for This method has been slightingly described as a kind of scientific bookkeeping "It is difficult ' says Stanley Jevons ' to imagine a less likely way of arriving at great discoveries The greater the array of facts the less is the probability that they will by any routine system of classification disclose the laws of Nature The answer to the claim that Bacon was the philosophic father of modern methods of scientific investigation is that none of the scientific truths established by the great masters of science can be made even to *appear* in correspondence with Bacon's methods Whether we look to Copernicus who preceded him or to Kepler Galilei Torricelli Pascal Gilbert and Harvey or to Newton De cartes or Huygens or to Thomas Young or to the chemists Black, Priestley, Scheele, and Lavoisier we find that discovery was achieved by a method quite different to that advocated by Bacon So dispassionate a critic of philosophy as John Grote remarks "I have not the smallest belief in Bacon s having reformed the method of discovery, believing rather that if he had had any success in that way in the manner he wished it would have been most calamitous for science ' And even with regard to the claim of Bacon to be the founder of inductive philosophy, Ellis one of the ablest of his editors asserts that the nature of the act of induction is as clearly stated by Aristotle as by any later writer, while Aristotle himself ascribes the credit to Socrates Perhaps the Baconian claim has never been more convincingly refuted than by Augustus De Morgan, at once one of the profoundest and subtlest thinkers of the nineteenth century "Modern discoveries," he says, "have not [illegible] facts, with subsequent dis[illegible] leduction of a truth thus [illegible] have suggested an hypothesis which means a supposition proper to explain them The necessary results of this supposition are worked out and then and not till then, other facts are examined to see if these ulterior results are found in nature Wrong hypotheses rightly worked from have produced more useful results than unguided observation But this is not the Baconian plan What are large collections of facts for ? 'To make theories *from* ' says Bacon, 'To try ready made theories *by*,' says the history of discovery '

Bacon's plan was purely mechanical He ignored the work of the mind in the constitution of knowledge He imagined that he had discovered a method by which scientific truth might be determined with absolute certainty and by a mechanical mode of procedure such that all men were capable of employing it "Our method of discovering the sciences is, he says "one which leaves not much to sharpness and strength of wit but nearly levels all wits and intellects And this opinion is endorsed by most writers of the empiricist school in complete disregard of the teachings of history Those who imagine that science requires nothing but the registering and classification of facts forget that the facts observed can only be connected and related by the mind and that the laws of nature are after all mental products from given data

Not only did John Hunter not follow the mechanical methods of Francis Bacon but it is the work of the mind which is the peculiar characteristic of his method and its chief glory Others could do as well as he the more mechanical part of his task, indeed much of it was done by others, but the suggesting controlling, coordinating mind was Hunter s which amidst the multiplicity of phenomena and of data apparently conflicting discovered unity amidst multiformity which is the special function of science

John Hunter s constant aim was to arrive at principles and he was distrustful of so called facts "The principles of our art he said "are not less necessary to be understood than the principles of other sciences, unless indeed the surgeon should wish to resemble the Chinese philosopher whose knowledge consisted only in facts In that case the science must remain unimproved until new facts arise In Europe philosophers reason from principles and thus account for facts before they arise

Hunter possessed every moral and intellectual qualification necessary for fruitful scientific research He had a large knowledge of facts based on an intimate acquaintance with the phenomena of organic nature He had a fertile imagination ready to suggest possible relations of those facts He had openness of mind and a conscientious scientific spirit which submitted every hypothesis to the test of observation and experiment Scepticism is the first condition of reasoned knowledge Hunter was not only observant but he was rationally sceptical and critical and he himself ascribed his success as a scientific investigator to the sceptical qualities of his mind He took nothing on trust He was always careful to distinguish between mere conjecture and reality and drew a sharp distinction between the actual results of an experiment physically performed and what might have been mentally anticipated

In pursuing any subject he says, "most things come to light as it were by accident—that is many things arise out of investigation that were not at first conceived and even misfortunes in experiments have brought things to our knowledge that were not and probably could not have been previously conceived on the other hand I have often devised experiments by the fireside or in my carriage and have often conceived the result, but when I tried the experiment the result was different or I found that the experiment could not be attended with all the circumstances that were suggested Here in a sentence we note the wide difference between the modern and the mediæval spirit in science. The alchemists performed experiments innumerable, but with them theory ranked above experiment and if experiment gave an unexpected result this was forced into an artificial conformity with the *aprioristic* theory. It was therefore, says Lange in his "History of Materialism," "essentially directed to the production of this previously anticipated result rather than to free investigation."

Many of Hunter's discoveries may be said to have been accidental but they were such accidents as happen only to those who deserve them, as Lagrange remarked of Newton. Chance may sometimes put us in the right way but chance alone does not takes us far. It was chance that showed to Ambrose Paré in the sixteenth century that gunshot wounds did not need the application of boiling oil as he had learned from his masters and as he himself at one time believed. Paré states that when he went to the wars in 1536 he had neither seen war nor gunshot wounds and only knew what he had read in John of Vigo who taught that gunshot wounds were envenomed and that the effect of the poison was only to be counteracted by pouring boiling oil into the wound. Paré, relating his later experiences, states that on one occasion there was not enough boiling oil to cauterise all the wounded, and he used instead for some of the cases a digestive made of yellow of egg, oil of roses, and turpentine. The shortage of the boiling oil caused Paré great distress of mind as he feared that those who had not had the application of the oil would die from poisoning. After a sleepless night he rose early in the morning and was surprised and rejoiced to find that those who had had the milder application had not only not died but that they were suffering but little pain and the wounds were free from swelling, whereas, those who had had the orthodox cauterisation were suffering severely from pain and swelling of the limb and from fever. Henceforth he decided to abandon the barbarous use of boiling oil. But not content with the accidental experience he proceeded in the true scientific spirit to test the alleged venomous quality of gunpowder and proved that not only was it non-poisonous but that it might be used with good effect to ulcers in order to dry them.

In a sense it was chance that disclosed to Hunter the establishment of collateral circulation after the ligature of a main artery. In July, 1785, Hunter tied one of the external carotid arteries of a stag with a view of studying its effects upon the growth of the corresponding antler. He observed that the pulsations of the vessels of the "velvet" ceased and that the antler, which was only half-grown, became cold to the touch. Hunter debated within himself whether the antler would be shed or be retained longer than usual. On examining it a week or two later, when the wound had healed, he found that the antler had become warm and was increasing in size. The question was—Had his operation in some way been faulty? The buck was killed and on examination it was found that the artery had been duly tied and was completely obliterated but that the circulation was carried on by vessels above and below the ligature, which had, under the new conditions, become enlarged and by their anastomoses had restored the blood-supply of the growing part. The knowledge of the establishment of collateral circulation was not new in the history of surgery. Blood-vessels had often been divided and tied in continuity and the nutrition of the limb had not been permanently impaired. Indeed, Celsus, writing in the first century of our era, distinctly states that after a division of a large artery the two ends should be tied and that repair takes place by anastomosis. But Hunter now saw from a new point of view the establishment of collateral circulation after the ligature of a large artery. He readjusted his conceptions. His sagacious insight discovered a deeper meaning in this chance observation and he conceived its applicability to the treatment of, at least, popliteal aneurysm. It so happened that there was a patient under his care in St. George's Hospital with popliteal aneurysm who had consented to undergo amputation. Hunter argued that if the anastomosing vessels in man would carry on the circulation after ligature of the femoral artery as it had done in the artery of the stag he could cure the patient's aneurysm and save the limb. Hunter performed the operation and in six weeks the patient left the hospital cured and with a sound limb. This operation, which has ever since borne Hunter's name, has been instrumental in saving hundreds of limbs and lives.

While the principle underlying this operation was originally suggested by a chance observation, its elaboration and perfection were only possible by a mind stored with clinical experience and emboldened by assurance gained through experiments on living animals. Hunter constantly submitted his observations to verification and, whenever practicable, to the test of experimentation, which Cossa describes as "observation carried to a greater degree of perfection." Hunter did not unnecessarily repeat experiments. It was an axiom with him "that experiments should not be often repeated which tend merely to establish a principle already known and admitted but that the next step should be the application of that principle to useful purposes."

While Hunter was intolerant of a state of doubt in small things as in great, if by any means decision was possible, he ever held his judgment in suspense if certainty was not attainable. Like all strong characters, he cared little for systems or consistencies of opinion. He followed wherever Truth should lead and by his very nature was always open to new and higher knowledge. To a pupil who asked with surprise whether he had not the year before stated an opinion on some point directly at variance with one he had just put forth he boldly replied: "Very likely I did; I hope I grow wiser every year." And again, "Never ask me what I have said, or what I have written; but if you will ask me what my present opinions are I will tell you."

In all his relations of life John Hunter manifested courage, candour, and tenacity of purpose. Truth he believed to be preferable to friendship and at the most painful crisis in his life did not shrink from putting into practice the Aristotelian maxim. Indeed, Hunter possessed not a few qualities in common with the great Stageirite. Hunter was not, of course, Aristotle's equal either in range of knowledge or in intellectual power. Aristotle did indeed take all knowledge to his province. Hunter had not the sweep of thought, nor the largeness of view, nor the grasp of logical and philosophical principles, nor the cyclopædic learning which distinguished Aristotle; but within his range Hunter's insight was as penetrating and as clear, and his zeal for knowledge was as ardent and as untiring, and his methods were sounder, more critical, and more exact.

Ordinary men are to be measured by the standard of their contemporaries but the greatest men are estimated by the influence they exert upon the thoughts and activities of those who follow them. Judged by either or both of these criteria John Hunter ranks amongst the greatest. The time in which he lived was a period of great intellectual and scientific achievement. He had for contemporaries amongst his countrymen Priestley and Black, Cavendish and Davy, Dalton and Thomas Young, Wollaston and William Herschell, and Hunter ranked high among the highest.

In attempting an appreciation of John Hunter's method I have suggested rather than explained the development and growth of the modern knowledge of physics, chemistry, and biology under the influence of the experimental method, but it has not been my purpose or intention to offer any defence of this method. To defend the use of experiment in physics and in chemistry would be manifestly absurd and, I assume, that in this place and before this audience it is equally unnecessary to offer an apology for its use in physiology and pathology. I opine, however, that it is within my province as Hunterian orator to anticipate the possible censure of some who would not hesitate in the sacred name of Religion to traduce the memory of Hunter because he practised experiments in physiology. John Hunter did employ the method of experiment. He employed it with no less zeal than with intelligence. He employed it not from idle curiosity, not from the promptings of vain-glory, nor for the purposes of worldly advancement: all that he had he gave to science. He employed it in the service of humanity and in the study of the nature and laws of life, and the knowledge which he thereby acquired he transferred to the domain of medicine and surgery and applied to the alleviation of sickness and suffering among animals no less than among men.

I pretend not either impiously to affirm or not less impiously to deny all the purposes of Infinite Wisdom in giving man dominion over the fish of the sea and over the fowl of the air, and over every living thing that moveth upon the earth; but we do know that throughout historic time man has not hesitated to capture, to subjugate, and to slay beast and bird and fish, for his pleasure, his sustenance, and his service. Was the lordship over the animals given to man only for the satisfying of his physical and sensuous needs? Is not the life more than food? Was it only with reference to man's bodily well-being that the question was asked: Are ye not of much more value than the birds of the heaven? Does the mind need no aliment? And is the veto to be applied only when animals are to be used for the purposes of elucidating the kindly functions of physiology or of disclosing the baneful secrets of disease?

The vicarious suffering and sacrifice of animals for the service and the salvation of man have obtained throughout the ages and constituted the basis of the elaborate ceremonial system of the ancient Israelites. In anticipation of the great Passover Moses directed the Israelites each to kill a lamb according to their families and to sprinkle its blood upon the lintel and the two side posts. "For the Lord will *pass through to smite the Egyptians*; and when He seeth the blood upon the lintel, and on the two side posts, the Lord will pass over the door, and will not suffer the destroyer to come into your houses to smite you." The complete purification of *one* leper and his reception back into society involved not only the slaughter of three lambs but the convalescent had to appear with two living clean birds one of which was slain while the other, still living, was baptised in the dead bird's blood and then allowed to fly away free. The principle of substitution was actualised in the ceremony of the scape-goat. At the annual Feast of Expiation a young bullock, two kids, and one ram were slain; and two goats were taken upon which lots were cast, one lot for Yahwè, the other for Azazel. The goat on which the lot fell for Yahwè was sacrificed for a sin-offering; but the goat upon which the lot fell for Azazel was presented alive, and when the high priest had symbolically placed upon its head the sins and transgressions of all the people, the goat was led into the desert there to become the victim of hunger and thirst and the prey of ravenous bird and beast.

Are these hecatombs to be regarded as of Divine origin and sanction, while the inoculation of a cat or dog, or it may be a rat, is to be denounced as a desecration and a violation of the purposes and will of God? Who will say but that in our day, as the Angel of Death passes through the land, seeing upon us the sprinkling of the immunising blood, takes that for a token, and is not suffered to come into our houses to smite us? "Dipt in his fellow's blood the living bird went free"; and so we, dipped in blood, aye, the blood of our fellow-man, as the annals of Medical Martyrology bear witness, we enjoy a growing freedom from plague, and pestilence, and noisome disease and in the fulness of knowledge the measure of our freedom will be full.

The Lettsomian Lecture

ON

FUNCTIONAL MENTAL DISORDERS.

Delivered before the Medical Society of London on Feb. 6th, 1905,

BY GEORGE H. SAVAGE, M.D. LOND., F.R.C.P. LOND.,

CONSULTING PHYSICIAN TO, AND LECTURER ON MENTAL DISEASES AT, GUY'S HOSPITAL, ETC.

MR. PRESIDENT AND GENTLEMEN,—In taking the subject of functional nervous or mental disorders I am going upon dangerous ground, for there is a vast difference of opinion as to what is meant by functional disorders. Before coming here I looked up what the Oxford Dictionary said about "function" and "functional." "Function is the mode of action which fulfils its purpose." Functional is defined as "affecting the functions only, not structural or organic." Maudsley, who is considered a purist in the English language, says "functional disease," not functional disorder, "such as epilepsy, chorea, and neuralgia." That, therefore, is the definition of the subject. I have to deal mainly with disorders that are not associated, directly at all events, with any recognised material change in the nervous centres. Functional has sometimes been looked upon as the equivalent of volitional; for instance, every hysterical person was looked upon as a person who was deficient in will; I shall have to refer freely to hysterical conditions, but it will not do to say that functional and volitional are equivalent.

Having given you some definition of function I will now give some definite of mental disorder. In mental disorder I include a great deal more than insanity as it is generally considered. The Right Hon. A. J. Balfour, at the meeting of the British Association for the Advancement of Science last year, pointed out the limitations of science; he pointed out that the organs of sense which were the gauges as it were of truth were themselves but the results, the evolved results, and the experiences of the very impressions which they had from without. Therefore the senses that were supposed to be the ultimate judges of all truth were themselves but the outcome of the impressions which were received from the *things which they were to judge. In the same way we talk* about sanity and insanity and the gauge of sanity is exactly in the same position that the senses are in relationship with science.

Functional disorders, the so-called hysterical, may be divided into certain groups. For instance, we have a muscular group, we have what might be called muscular hysteria, in which there is paraplegia, monoplegia, or aphonia. Or you may find defective control as in those cases of malleation and monotonous movements which are met with in truly hysterical conditions. The functional relationship of some of these disorders with their nervous and mental disorders is shown by what I have called alternation. A patient who was admitted into Bethlem Hospital in a maniacal condition was found one day to be paralysed in her lower extremities and perfectly sane. Later she again became maniacal and at once lost the paraplegia; again later she lost the paraplegia and became maniacal. It may be the same with the muscular activity that is met with in some cases of disordered hysterical movement.

Passing from the hysterical muscular conditions and allied mental stages one has to recognise the sensory ones. And it is interesting to note the various paræsthesiæ and anæsthesiæ that are met with in *hysterical cases*. Among the more [illegible] temporary mental disorder in which there is no direct nervous central change to be discovered.

Comparable with those cases of loss of feeling are those patients who have done peculiar things and yet say they have no memory of them whatever. I believe a large proportion of hysterical people have a direct memory of what they have done but I am equally certain that there are a number who are as completely free from memory as they are free from power to move when they are hysterically paraplegic. There are endless conditions that are inexplicable from our point of view and yet certainly are not to be traced to any definite central disease of the nervous system. The sudden cures that occur under faith-healing and at Lourdes are cases that are associated with functional and not organic nervous disorder. One cannot understand either the one or the other curing an absolute disease and I would propound this question: Are all sudden cures occurring in any forms of mental or nervous disorder to be looked upon as evidence tha [illegible]

I [illegible] tion bet [illegible] as mat [illegible] re- cog [illegible] or disorders that may be still called functional. If, for instance, the person who suffers habitually from hay fever during the hay fever season becomes melancholic or disturbed mentally he does not have hay fever though living under exactly the same conditions as before this would point to both of these disorders [illegible] The same may be said o [illegible] for a patient who has [illegible] attacks to keep quite free of them during the time he is in the asylum and when he gets well they return. It has to be recognised that certain other alternations take place that can hardly be looked upon as purely associated with functional disorder; that a man suffering from melancholia should lose that melancholia when he has a severe attack of gout; that another individual should lose his maniacal attack when he has an attack of rheumatic fever is hardly, I am afraid, to [illegible] rheumatic fever are [illegible]

[illegible] t Commission on the Education or the Care of the Feeble-Minded is bringing before all of us who are interested in mental nervous disorders crowds of individuals who are out of harmony with their surroundings, individuals who have no disease of their body, whose senses are perfect, who you may say have a judgment which is defective. Quite so; but at the same time each of our judgments is defective in some particular way probably. There is a large amount of mental disorder that is functional in so far as it prevents the individual from fulfilling his functions, taking his ordinary position in life. And if he fails to fulfil this purpose there is a failure in the performance of his functions.

The next thing to which I would refer is disorder of function that may lead to insanity. I think perhaps it might be well for me, in a few words, to quote two authorities on the question of function and its relationship to organs. Bristowe pointed out in relationship to functional muscular disorders that the affections here referred to are limited to a single muscle, or to part of a muscle, or to groups of muscles, and occur only or mainly at the time when "certain accustomed specific actions in which they are engaged are in process of performance, the affected muscles apparently acting normally under all other conditions and in other respects seeming to be fairly healthy." If instead of muscle mind is substituted, that covers exactly what I am maintaining. The other perhaps will be looked upon as more eccentric but more characteristic. The late Dr. Sutton in his Pathology says: "It is abuse of natural function, extreme abuse and restraining, hindering and interfering, that bring about disease. Every age of life is characterised by systematic interference. It is through our detestable systems that human misery comes about. Interference is a mistrust of functional activity. Once when I was with Sir William Gull he said to me, 'Sutton, human nature has never had a fair chance,' and it is true. The more I see of the human body the more I admire it for being able to endure so much and suffer so little. The study of pathology reveals that one and all of the functional blessings of man are abused into disease. When we are born we cry that we are come to this great stage of fools, says Lear. The mouth of the new-born babe is stuffed with sugar and butter and its belly crammed and its legs are not allowed to kick. It has indeed come on a stage of fools."

So you see in quoting from Dr. Sutton I am supported in my contention that a great deal of mental disorder depends rather upon the outside conditions than on the central conditions, in fact, in certain cases the patient is not so mad as his surroundings. Therefore I maintain that disorder of function leads not infrequently to real disease. Of the conditions said to lead to insanity the solitary confinement of the prisoner has been scarcely substantiated, but those who have been in the wards with me know how frequently I have pointed out the natural evolution, say, of "governess's disease," the exaltation of ideas, the feeling of grandeur and well-being that may naturally grow from the surroundings and not be innate in the individual. There is the governess, highly educated, very likely over-wrought, perhaps sprung from a lower station, who passed into a higher grade where she is a teacher and where she is recognised as a teaching machine, not as a human being, where she has every inducement to think highly of herself and is not able to associate with any of her fellows. The result is that she falls out of relationship with her environment, that she believes herself to be some important person.

Again, another form I have named "widow's disease." An English widow of middle age is left with a small amount of money and a family. She has to live a narrow cramped life. Things are thrown upon her which she never had to do or think of before and the consequence is that she is out of harmony with her environment and the environment tends to the mental disorder that may be associated with one form of depression or with another form of delusional insanity that people are scandalising her or taking her character away. In the same way you have only to suggest to certain sensitive minds a certain line of thought and it is surely not their brains which are responsible, primarily at all events, for the disorder which may arise.

To pass on to another group altogether, there are the so-called neurotic, the unstable people, you may say, who are pathological specimens from the first; possibly so; I can only say that the world works on two wheels, I believe—the neurotic and the gouty—and I am inclined to think that the neurotic type has to be considered not as a pathological entity but as a variety that may tend to be good, bad, or indifferent. They are characterised almost wholly by a too ready reaction to their environment. They have what might be called exaggerated mental reflexes and here we come to the impulsive classes. I suppose we have not got far enough in pathology. Though we talk about nerve currents and nerve storage as if we knew all about the batteries and the wires that conduct them, and though we talk about discharges in epilepsy and the like for convenience, yet I fail to recognise that as a material pathology. And when referring to Maudsley's definition of functional disease, including epilepsy, I feel strengthened in my contention that I am right in including the neurotic. The neurotic interests one in many ways. First of all his instability, his tendency to impulse. The neurotic child often has a dread of heights and has a dread of moving bodies. The neurotic adult often has the same. The healthy adult when he gets run down may have the same. The senile person may have exactly the same instability, this tendency to exaggerated mental reflexes. It is a very little step between the nervous dread and the extreme nervous sensibility that one meets with in certain cases. I have not time to consider what may be compared to impulses such as obsessions, fixed ideas—which morbid ideas may be recognised by the patient to be morbid.

Now comes perhaps one of the most difficult groups of cases to understand and I must claim for this group that they should be considered as functional, not as organic. They are not common cases. During one period they are, as you might say, without control. They say exactly what comes into their minds or as it is expressed on the tip of their tongues, whether it is polite or impolite, but there are no delusions, no hallucinations. Then a shake, or perhaps not a shake, and the whole thing is changed and they again become sane. Therefore are you not to believe that cases of that kind are and must be considered from some other point of view than that of disease of cells of the brain?

Before concluding I must refer to arrest of function. I remember a man who for an operation was put under chloroform. After recovering from the chloroform he seemed to be dull and apathetic. He had no delusions but he remained where and how he was placed. If he was dressed he remained dressed; undress him and he would stop in his nightgown without getting into bed. Put him into bed and he would remain there. He was simply automatic and remained in that condition for several weeks. He then woke up quite suddenly and was himself again. Then, again, I have seen following shock somewhat similar conditions in which the whole nervous functions seemed to be arrested without being destroyed or affected in any way beyond that.

To sum up my opinion, then, I would say that there are many cases in which disorder of mental function cannot be directly associated with material change in the brain or nervous system. That many cases may depend upon alterations of nutrition of a temporary character in the nerve centres, central or peripheral, I admit. That besides this there are certain disorders which depend on the disharmony existing between the nervous system of the patient and his surroundings. Such disharmony may be original and ineradicable and is met with in certain persons who seem to have been born out of due time, being only suited to primitive states of civilisation. We have to consider that there may be misjudgments of parts of the nervous system, want of will or directing power; and in saying this I do not wish to make it appear that I believe the will to be an isolated part of mind. Yet one constantly meets with instances in which there seems to be want of proper adjustment of what have been called the functions of mind. In obsessions there may exist perfect knowledge and all the necessary constituents of the mind, yet their association may be morbid, and the result may be unreasonable and impulsive action, unreasonable belief, or obsessions of ideas. Besides these we have considered cases of sudden cure and compared them with hysterical attacks, aphonia and paraplegia, which may also be recovered from suddenly. The whole subject, I allow leads, and must lead, to much difference of opinion, but if I have succeeded in laying before you some of the results of my experience I shall feel satisfied. I recognise as fully as any of you the difficulty of my position. There was a time when "functional" was a term which covered and seemed to supply the want of knowledge, but as time passed on more was wanted. But I still think the wise man investigates; it is the savage and the lunatic who are ready with explanations. Science is organised inquisitiveness and its results. But I have little patience with so-called science that looks upon everything as already within the scope of explanation. Functional disorders, not functional diseases, depend on causes, like everything else in this world, every result has certain antecedent conditions, but when we come to consider insanity I would repeat here what appealed strongly to my Guy's class of former years, the statement that there is no such thing as insanity. Insanity, mental disorder, depends as much on the surroundings as on the individual's bodily condition. If we were all turned out like American watches, by the million, all alike, with changeable machinery and parts, it would be different. In so-called insanity, and indeed in humanity, we have to deal with constantly changing environment, different powers of adaptation, and I therefore say at once that I cannot expect to have a clear morbid pathology for all conditions which do not fall within the conventional lines of sanity.

THE EARLY SYMPTOMS OF INSULAR SCLEROSIS.[1]

E. HOBHOUSE, M.A., M.D. OXON., F.R.C.P. LOND.,
PHYSICIAN TO THE SUSSEX COUNTY HOSPITAL, BRIGHTON.

I HAVE chosen this subject because it is one of great interest and importance to all of us and it so happens that I have seen a considerable number of cases in the last few years which have impressed this on me. It is from the point of view of general medicine that I propose to speak to you, not with any pretensions to be a neurologist, because we do not in provincial towns of the size of Brighton get sufficient opportunities for the systematic study of neurology, and in these days it is impossible without that systematic study to do more than keep in touch with this subject, which is the most exacting of all the special branches of medicine and the most difficult. But it is just from the general medical standpoint that insular sclerosis is of such importance and for three good reasons. 1. Because it is, so far as my limited experience goes, considerably the commonest of all the chronic diseases of the central nervous system. 2. Because owing to the great diversity of its symptoms it may come first in the early stage under the notice of any man whatever branch of medicine he practises, whether he be a physician, or a surgeon, or a gynæcologist, or an aurist, or laryngologist, or ophthalmic surgeon. 3. *Because it is by no means easy to recognise in* the early stages and is extremely apt to be confounded with hysteria, if, indeed, it be not more correct to say that hysteria is not rarely the prelude to insular sclerosis. If for no other reason, insular sclerosis might well claim our attention as being the only disease which can be said to mimic hysteria, that great simulator of so many diseases. It is exceedingly difficult, as I shall try to show you later, to say in some cases where hysteria ends and insular sclerosis begins and as the disease is often spread over a large number of years it may be impossible to get a continuous clinical history. But it is [illegible] the diagnosis as early as possi[illegible]nd, to save a patient suffering [illegible]entral nervous system from being treated as a wretched hysterical creature and, on the other, to prevent a truly hysterical case from lapsing into chronic invalidism for want of active measures. I may say that it is the first of these two events which is much the most likely to happen.

1. I will now take in order the three reasons which I have given for the importance of insular sclerosis, and first as to its commonness of occurrence. I have gone through my out-patient records for the past five years and find that during that time, I have seen nine cases in which I was absolutely certain of the diagnosis, usually after watching them for [illegible] in which the diagnosis was [illegible] ave seen 5000 new cases of [illegible] so that deducting 1000 for renewed letters and cases in which I did not make the diagnosis myself the average is about 2 per 1000. In the same period I have seen, or at least recognised, only six cases of paralysis agitans, five of locomotor ataxy, two or three of general paralysis, four of cerebral tumour, and a few odd cases of syphilitic disease of the cord, progressive muscular atrophy, and some obscure nerve lesions, including a good many which were traceable to lead poisoning. It will be seen, therefore, that in this list insular sclerosis is considerably the commonest of all the important chronic diseases of the central nervous system, so far as it is permissible to make a deduction from the comparatively small number of cases. It is true, of course, that the diagnosis in the out-patient room is often hasty, but I may say that I have had nearly all these cases in the wards for a short time for more careful observation and that in the two or three which I have not thus watched the disease was quite unmistakeable. I have a strong belief that I have probably overlooked a number of examples and that the list would be considerably larger if I could review many of the cases which I have labelled neurasthenia, hysteria, and neurosis; also that it would be longer relatively to other diseases of the nervous system which are less easily overlooked and less liable to be masked by hysterical symptoms. To these nine cases I have added six that have been under my care in private for varying periods. Insular sclerosis therefore is, I believe, commoner in the out-patient room than the much more often talked of [illegible]

of hysteria, which is so easy in insular sclerosis, very improbable in tabes.

Many cases of insular sclerosis are missed simply because the human mind moves naturally along the paths of least resistance and therefore satisfies itself with the diagnosis of hysteria, which may be fairly correct if the further possibilities of the case are not overlooked; in tabes, of course, it is easy enough to overlook the correct diagnosis where the only symptoms present are lightning pains, or some visceral crisis, or an ocular palsy, but it is rare for any alternative diagnosis to be present as a possible one in the same way as the diagnosis of hysteria is present in insular sclerosis. It is probable, of course, that the figures would be quite different in a hospital for nervous diseases only.

2. I will now come to the second reason which I give for the interest of insular sclerosis—viz., that the diversity of the symptoms may bring it under the notice of anyone, whatever branch of medicine he practices, so that all ought to be alive to the significance of the early symptoms or they will be liable to make serious mistakes. It is unnecessary to describe the chief symptoms of the disease as given in Charcot's classical picture, now some 35 years old; you are all of you familiar with the spastic gait, the tremor (much increased by exertion), the scanning or jerky speech, the [illegible] which go to make up the symptoms of the [illegible] is our debt to Charcot [illegible] separated the disease from the neurological mud heap, it is none the less somewhat of a misfortune that we were most of us brought up on that classical picture and therefore may fail to recognise the disease in its more irregular forms as we know it to-day.

If we waited to make a diagnosis of insular sclerosis until the patient had all the symptoms which I have enumerated we should make it but seldom and we must be content if we get one or two of these symptoms to confirm a diagnosis made partially on other grounds. Nor need I detain you, with a discussion of the pathology of the disease or the disputed question as to whether the morbid change begins primarily in the vascular, nervous, or interstitial tissue. Whichever it be the result is the same—viz., the formation of islets of sclerosis of a peculiar character in various parts of the brain and spinal cord. The important point for us as *regards the diversity of symptoms is this, that though there* are certain seats of election where the change most commonly commences, the distribution is, speaking generally, a random one and therefore the initial symptoms may be of almost any character. As a matter of fact the majority of cases begin in one of two or three different ways. Most patients go first to the physician complaining of weakness in the legs, or of one side, or one limb, or of nervousness and trembling, but a considerable proportion go first (as is also the case with tabes) to the ophthalmic surgeon, often at a date considerably anterior to the appearance of any general symptoms. This point should always be inquired into, as the patients themselves do not connect the eye symptoms, which are usually of a transitory character at first, with the general disease and with the poorer class of patients they are [illegible] forgotten.

I [illegible] cases on which this [illegible] far as I have

---

[1] A paper read before the East Sussex Branch of the British Medical Association.

TABLE GIVING PARTICULARS OF 16 CASES OF INSULAR SCLEROSIS.

No.	Sex.	Primary symptoms.	Secondary.	Age at onset.	Causation.	Duration at first visit.	Sphincters.	Optic disc.
1	M.	Weakness of leg and arm.	—	37	? Syphilis.	6 months.	Yes.	*Nil.*
2	F.	Pain in right arm and knee; 9 weeks' loss of power in left hand and foot.	1 month later failure of sight in right eye.	30	*Nil.*	4 ,,	,,	,,
3	F.	Ophthalmoplegia externa; suddenly disappeared in 4 months.	Sudden attacks of loss of power in legs.	44	Worry.	2 years.	,,	Marked pallor.
4	F.	Weakness of legs; right first recovered and relapsed.	—	26	Pregnancy.	3 months.	,,	*Nil.*
5	M.	3 years before stiffness of the left leg and foot.	18 months of failure of right eye.	21	*Nil.*	3 years.	,,	Some pallor.
6	F.	Trembling and weakness.	—	20	,,	6 weeks.	No.	—
7	F.	Weakness of legs and tremors.	—	About 30.	? Syphilis.	5 years.	Yes.	Pallor of discs.
8	M.	Stiffness of left leg.	Tremor of speech and weakness of the left arm.	22	Blow over the right motor region.	3 months.	,,	(?)
9	M.	17 years' weakness of legs.	7 years previously diplopia and again 4 months previously.	23	Syphilis.	17 years.	,,	*Nil.*
10	M.	6 months very shaky.	—	47	Lifting very heavy weights.	6 months.	(?)	(?)
11	F.	6 weeks' weakness of legs.	—	11	*Nil*	,,	Slight.	*Nil.*
12	F.	10 years previously severe vomiting lasted 3 weeks; diplopia; anæsthesia of the right side.	After diphtheria weakness of right leg.	35	Anxiety and diphtheria.	10 years.	Yes.	Pallor.
13	F.	10 years previously sudden loss of vision, returning gradually after a few hours.	4 years ago weakness of legs.	39	Anxiety and chill.	,,	Slight.	,,
14	F.	2 years before weaknes of legs.	—	21	Malarial fever; abortion.	2 years.	Yes.	Yes.
15	F.	3 months before failure of vision in left eye, returning in 24 hours.	Tinnitus like bell booming.	30	Shock and diphtheria.	3 months.	,,	Slight pallor.
16	M.	6 years previously sudden fall in the street.	Diplopia.	69	Anxiety and hard work.	6 years.	,,	?

Note.—Case 11 eventually turned out to be a case of spinal caries.

been able to make out, what the early symptoms are. Of the 16, then, three began with purely ocular symptoms—viz., Case 13, in which the ocular symptoms antedated the others by six years; Case 3, in which they preceded by two years; and Case 15, in which they were three months prior. Besides these diplopia accompanied the earliest symptoms in Case 12, which were rather of a complicated character and suggested hysteria. In four other cases the ocular symptoms were the next to appear at intervals of one month, 18 months, and ten years after the first trouble, the date in the fourth case being unknown. The three cases in which the ocular symptoms came first were all seen in private and had all consulted ophthalmic surgeons who have been kind enough to give me their notes. I should add that in no case was the true nature of the disease suspected by anyone until some time after the appearance of the eye symptoms. In all the other cases the first symptom of the disease was some form of loss of power or disturbance of sensation, chiefly the former, in one of the limbs or both legs, generally of a transitory character and at first rapidly recovered from. One, Case 13, began with an attack of vomiting (amongst other symptoms), analogous, as Charcot long ago pointed out, to the visceral crises of tabes. As regards other symptoms it may be noted that the sphincters were affected to some extent in a very large proportion of cases, often quite early.

There is one symptom which I have never seen noticed anywhere but which has been so frequent in my female cases that I cannot help thinking it to be a result of the disease—viz., menorrhagia. In one the hæmorrhage was terrific at two or three periods, soaking the bed, and in at least four others it was severe. It is *a priori* probable that a disease which so often affects the lumbar centres should have some effect on the uterine functions. In this event a patient may consult a gynæcologist first, as I believe actually happened in one of my cases, No. 14.

In one of the cases above mentioned in which the patient first consulted an ophthalmic surgeon the next symptom that appeared was persistent and very distressing tinnitus for which she came to consult me. Finding nothing wrong with the ears and as no drug seemed to do any good I sent her on to an aural surgeon who reported that it was probably of nervous origin. I mention this because, though tinnitus is a rare symptom, it might easily be the first to appear and the patient might go in the first instance to an aural surgeon. Again, aphonia may be an early symptom and the patient may consult a laryngologist for loss of voice. Lastly, a patient may consult a surgeon for supposed injury to the spine or for some bladder trouble, though this rarely appears till later in the course of the disease. In one case, of which I shall give you more details presently, as being a very typical case of slow hysterical onset, the patient was for some years under a surgeon for various hysterical phenomena, beginning with contracture simulating talipes equino-varus.

Of course it is very difficult to say at what time the existence of the disease might have been recognised in these various cases; as a rule it is not even suspected and I must own that in the case of the female who came to me for tinnitus it was some time before I recognised the real nature of the trouble, and then only because there was difficulty in walking. The total duration of the disease in this instance was only nine months. It is clear, I think, from what I have said that it is necessary for us to examine with some care those cases in which there is temporary loss of sight in one or both eyes, or diplopia, or transient aphonia, or difficulty in walking, or sudden falls without any apparent cause to account for them, the patients as a rule complaining that their legs suddenly give way. We must not put them aside as merely hysterical because they are associated with a highly emotional manner or with other symptoms which are usually regarded as hysterical. The truth is (as Dr. T. Buzzard, who has done more than anyone else to elucidate the relations between hysteria and insular sclerosis, has pointed out) that some of the very symptoms which formerly were regarded as typical of hysteria should now arouse our suspicions and lead us to think that in all probability the case is not one of hysteria, especially those symptoms connected with the eyes.

3. This leads me on to my third reason for insisting on the

importance of insular sclerosis—viz, the difficulty of diagnosis and the confusion with hysteria It is in fact this liability which makes the diagnosis of insular sclerosis of such great importance As regards treatment by drugs and other measures unfortunately it cannot be said that we can do much but on the other hand we do a good deal of harm to the patients by treating them as hysterical and insisting on constant effort and by exposing them perhaps to the reproaches or ridicule of their family, on the ground that they could easily do things if they would only attempt them

The most misleading thing about the early stage of the disease is the transitory nature of the symptoms, it is this which is really typical The patients can see one day and be almost blind the next or they can walk fairly well one moment and the next be unable to move from their beds The symptoms may come on with startling suddenness and depart almost equally suddenly It is not surprising that symptoms which seem to be so entirely capricious in their coming and going should be thought to be hysterical for it is difficult to explain them on the theory of any organic lesion and I do not know that any adequate explanation has yet been given But it is quite certain that an organic lesion exists, if the progress of the case be watched the symptoms which were once transitory become more or less permanent the vision gradually becomes worse and worse and the optic nerve, which at first showed slight pallor, may become entirely atrophied The difficulty in walking persists and leads to contracture the tremor which used to be intermittent remains constant when anything is attempted and makes all occupation impossible There is no longer any question of our having to do merely with some functional disturbance and if the case goes to a fatal termination we *are certain of finding the characteristic* lesion in the brain and spinal cord save in very rare instances

There is another thing which adds considerably to the difficulty of diagnosis—viz, that many of these patients have what we are pleased to call a typically hysterical manner—i e they are very emotional and easily moved to tears or laughter and the voice may have that tremor which is often found in highly nervous people but here may be a symptom of the disease This is by no means the case with all but it is so with not a few and adds considerably to the probability that the case will be regarded as hysterical

Dr Buzzard has pointed out the chief criteria on which we must rely for a differential diagnosis and as I cannot improve on his account I will merely recapitulate what he says Of course there is no difficulty in a fully developed case of the disease in which the tremor, so called scanning speech both much accentuated by effort the spastic gait increased reflexes nystagmus &c are all present but it may be years between the first appearance of the disease and the establishment of conclusive symptoms of this kind and meanwhile the diagnosis will hang in the balance sometimes inclining to hysteria and sometimes inclining to organic disease according as the various symptoms are active or remittent at the time In Dr Buzzard's words ' Until such symptoms as the above make their appearance in a case about which doubt has existed I do not think that we can as a rule safely pronounce a diagnosis of insular sclerosis But in a case in the history of which paresis has occurred in one or more limbs with spontaneous recovery and repeated recurrence of the symptoms in the same or another part together with a history of amblyopia either temporary or persistent my experience would lead me to diagnose insular sclerosis in the absence even of the symptoms first enumerated "

There is one reflex symptom to which Dr Buzzard draws attention in a later paper and about which I should like to say a few words because it is sometimes present when all the others are inconclusive and is almost if not absolutely, conclusive evidence of organic disease of some kind—i e the "toe phenomenon When the sole is stimulated the normal response is, except in infants who have not walked flexion of the toes on the foot at the metatarso phalangeal joint, in pathological conditions where the fibres of the pyramidal tract are involved at any point this flexion is replaced by extension of the toes especially of the great toe Babinsky, who discovered it never found it except in cases of organic lesion and Dr Buzzard confirms this I have tried it in a very large number of cases and never found it present where organic disease of the nervous system was unsuspected except once in a case of diabetes, where it may possibly have existed unsuspected It must be added however that its absence proves nothing and that it is uncertain in its appearance being present at one time and not at another It has never been known to occur in any case of purely functional disease and is therefore a very valuable symptom in the *diagnosis of hysteria, the most valuable of all the reflex* symptoms

I will now give you an account of one or two cases beginning with one which is a very good example of the difficulty of diagnosing between hysteria and insular sclerosis and in fact leads one to wonder where the one ends and the other begins

CASE 7—The patient a woman aged now 39 years, has been several times in the Sussex County Hospital, besides one or two London hospitals and was always regarded as a hysterical patient As far back as 1878 she was under the care of Mr W Turner for contracture simulating talipes equino varus Under chloroform this disappeared but reappeared on her return to consciousness When this leg was put up in plaster the deformity appeared next day in the other leg At another time she was taken in for a superficial ulcer on the abdomen which was almost certainly caused by some injury she herself had inflicted probably with acid She was also admitted at other periods for various ailments which were always regarded as hysterical I saw her first some two years ago, some five years since her last visit to hospital and came to the conclusion that she was suffering from insular sclerosis, a fortnight ago I again saw her a typical example of the last stage of insular sclerosis—bedridden and with excessive tremor complete loss of sphincter control and with those mental changes which are often found in that disease The chief points about this case are briefly these 1 Its very long duration 2 The fact that the first *symptoms of organic disease were preceded by symptoms* which are universally regarded as functional in their character and which undoubtedly occur in hysterical persons who never show any signs of organic disease and are proved by post mortem evidence to be free from it There was therefore every reason to believe that the case was hysterical and that the weakness of the legs for which I first saw her was an hysterical paraplegia but with this there were incontinence of urine and an amount of tremor with ocular symptoms which made it impossible to regard the case as functional At the present moment three years after her condition is as I have said quite unmistakeable We must conclude therefore that this was a case in which true hysteria characterised not only by the physical phenomena but by that psychical condition which leads people to inflict injuries on themselves preceded insular sclerosis

Charcot mentions cases in which hysteria preceded the disease but does not say how many he saw, and it is clear from his classical account of it that he only recognised the disease in its established form and therefore probably did not lay much stress on the connexion with hysteria or the difficulty of diagnosis It is important to distinguish between *those cases in which undoubted symptoms of* hysteria come first and those in which what are really symptoms of insular sclerosis are mistaken for hysterical troubles and only recognised subsequently as the prodromal symptoms of insular sclerosis The latter is much more commonly the case Some of these symptoms are such as are found at times in undoubtedly hysterical patients and these are now believed by the best authorities to be really indicative of insular sclerosis though not conclusive without other evidence I will mention one or two cases of this character

CASE 13—The patient a woman aged 48 years had in 1886 an attack of sudden amblyopia which passed off completely in 24 hours in the left eye but affected the right for several days In 1892 after exposure to cold she began to suffer from weakness *of the legs which had increased* slowly and difficulty of vision which was very variable She also showed some mental changes becoming irritable suspicious, and forgetful Her case had progressed very slowly and she was still able to get about but the ocular symptoms and condition of the reflexes with some loss of sphincter control left no doubt that the case was really one of insular sclerosis with very slow hysterical onset This case was one with rather unusual onset, the anæsthesia and vomiting were regarded as hysterical and subsequent events alone have shown their true significance In this case too the disease has made very slow progress and several of the classical symptoms are still absent but no reasonable doubt can exist as to the nature of the trouble

One word as to causation. In many cases no cause can be assigned but anxiety, hard work, and, in Case 10, severe physical exertion seemed to be potent factors. Case 8 is interesting in that the symptoms seemed to follow directly on a blow, the scar of which could be felt over the right motor region and commenced first in the left leg. In this case the disease progressed very rapidly and in three months showed most of the typical symptoms. Diphtheria in two cases and malarial fever in another seemed to be to some extent responsible at least for an aggravation of the disease and pregnancy, as in Case 4, is well known to be injurious.

In conclusion, gentlemen, I must ask you to excuse me for the inadequacy of this paper, but I hope that I have said enough to show you that the subject is not a barren one and that it is of real importance in cases which appear to be hysterical at least to have a suspicion that they may have an organic basis. I hope, too, that I have shown you that it is a disease of which everyone ought to have some knowledge whatever his branch of medicine and be able to recognise the symptoms from his own point of view as at all events suggestive. We do not as yet know how early it is possible to recognise the disease because it is as a rule difficult to get back to the beginnings of it. It is just in this matter that we are able to do something to assist the nerve specialist because we often see cases over prolonged periods which he only sees rarely and the earliest symptoms usually come under our notice rather than that of the specialist.

If we are ever to do anything to combat this formidable disease, which is very possibly increasing in frequency with the general increase of nervous strain, to which in some instances it is undoubtedly due, we must take it at its commencement and to do that we must learn as much as possible about its earliest symptoms. I would therefore appeal to all those who may have the opportunity to make as accurate a study as possible of the cases which they may come across and especially to note and to report any with abnormal onsets or in which the causation seems particularly clear. Nervous diseases, largely on account of their hopelessness, are not a very tempting study to the man who is not a specialist, but most valuable aid in the elucidation of disease may be rendered by him and to him in the end the specialist must look for much of the most essential information about the history of cases such as those of insular sclerosis.

Postscript (1905).—Of the cases mentioned three are dead —viz., 14, 15, and 16—but all were private cases and in no case was a necropsy obtainable. Of the others Case 11 subsequently developed spinal caries, though she had no symptoms of it at the time and was shown two months later at a London hospital as a case of spastic paraplegia. Of the remainder nearly all have been seen subsequently, especially Cases 2, 3, 4, 5, 7, 12, and 13. In all the course of the disease has confirmed the original diagnosis but it is interesting to note that the prognosis both as to duration of life and to recovery from mental and physical symptoms has been repeatedly falsified. Case 7 who seemed to be in the last stage of mental and bodily decrepitude, is still alive and sufficiently recovered to recognise me at my last visit and to converse rationally. Case 3 is practically bedridden but quite clear in mind, though emotional; she can hardly use her arms owing to tremors and her eyesight is very bad. Case 12 can get out occasionally, though for a time she seemed absolutely helpless; she is emotional and irritable but quite clear in the head and can use her hands perfectly as a rule, writing quite legibly, and her eyesight is very fair.

Two points seem to be clear: 1. That the slower the onset of symptoms the more hopeful is the prognosis as to remissions and the less likely is any given attack to be finally crippling to mind or body. 2. The fact that the earliest symptoms are cerebral does not necessarily imply that those will be specially predominant later; in both the last cases ocular symptoms came first but the brain and upper cord are comparatively little affected, whilst the paraplegic symptoms have been prominent for some years.

Brighton.

VACCINATION GRANT.—Mr. John J. Huey, L.S.A., public vaccinator of the Mexborough, Adwick, and Bamboro' districts of the Doncaster union, has received the Government grant for successful vaccination.

SABOURAUD'S METHOD OF RINGWORM TREATMENT.

BY J. L. BUNCH, M.D. LOND., M.R.C.P. LOND.

UNTIL quite recently the treatment of ringworm has been tedious, trying, and uncertain. Many medicaments and chemical substances have been vaunted as cures; lotions, ointments, and sprays of various nature have been brought forward as infallible, but the fungus has shown itself to be possessed of an extraordinary amount of resistance when once it has invaded the hair of the scalp. The difficulty of the problem depends on the fact that most of these chemical substances and all antiseptics are capable of killing the ringworm and all other cryptogamic parasites *in vitro*, but no antiseptic can penetrate the hair follicle to a greater depth than one millimetre. The hair of a child, however, is implanted in the skin up to a depth of four millimetres, and the parasite of ringworm involves its root down to the terminal enlargement of the hair bulb. The parasite of favus is similar in that it also is inaccessible to antiseptics, but the disease can be successfully treated by five or six epilations repeated at intervals of a month. This method, practicable in favus because the hair remains solid, is impracticable in ringworm because the affected hair becomes fragile and breaks. It cannot be pulled out entire but breaks at its most diseased portion and the fungus spores remain behind with the root. The hair continues to grow but the parasite continues to develop in proportion to the growth of the hair.

The parasite of ringworm is not always the same and from the point of view of treatment by chemical agents[1] a considerable degree of importance attaches to the variety of fungus which is causing the disease. In England the great majority of cases are caused by the microsporon Audouini—in Fox and Blaxall's cases from 80 to 90 per cent., other observers giving 80 to 96 per cent.—whereas in Paris the microsporon only causes 60 to 70 per cent. of the ringworm cases. In the large spored variety the distribution of the ectothrix and endothrix varieties differs, Sabouraud, for instance, having published a series of Paris cases in which the megalosporon ectothrix was absent in all the scalp cases, although it was found to be the cause of all the cases of ringworm of the beard. In a series of cases published by myself[2] the origin of certain cases of ringworm from animals was proved and in these cases the megalosporon variety was found to be much the more common. Little importance attaches from the point of view of treatment to the question whether the epidermis is attacked before the hairs or *vice versâ*, although my investigations have shown the former to be the case; much more importance attaches to the nature of the fungus. Thus the microsporon is much more resistant to treatment than the megalosporon, some cases in children being so obstinate that they persist, in spite of the most active treatment, till puberty and then the disease disappears for some unknown reason, and in any case we cannot fix a limit within which a cure may certainly be effected.[3]

Such, then, being the result of treatment by chemical substances and the root of the hair being inaccessible to antiseptics, the solution of the problem could only be found by discovering an agent which was capable of inhibiting for a time the function of the papilla from which the hair grows. Such an agent is radiotherapy. During the last few years immense improvements have been effected in the technique and methods of application of radiotherapeutics, but it has been well known for some years that the application of the x rays causes the hairs to fall out, and in 1896, one year after Roentgen's discovery, Freund attempted the treatment of ringworm and various forms of dermatosis by radiotherapy. Since then numerous attempts have been made to establish a definite method of treatment of cases of ringworm but the absence of satisfactory methods of measuring the radiations employed and the resulting accidents have made many experimenters timorous. Moreover, the large number of exposures necessary (as many as 40 have been quoted for a single case) made the treatment of ringworm by radiotherapy of no practical value The unsuccessful results were all due to the same cause—uncertain dosage of the rays owing to an absence of measurement or imperfect measurement of the quality and quantity of the rays applied to the diseased area Of these two measurements that of quantity is more important than that of quality, inasmuch as the therapeutic reaction depends essentially on the quantity of rays absorbed Other factors undoubtedly enter into the calculation, such as the age of the patient, the position of the cutaneous area to be treated, the nature and the degree of the lesion, to say nothing of idiosyncrasy, but these biological factors are of minor importance as compared with the physical factor of the quantity of rays absorbed In England the possibilities of radiotherapy as applied to the treatment of ringworm have not been grasped because no satisfactory attempt has been made to measure the dosage of the rays or to proportion to each case the exact amount of therapeutic agent necessary Measurement of the current supplied to the tube by means of an ampèremeter is not sufficient, the rays generated by a tube vary from time to time according to surrounding conditions and according to the internal conditions of the tube—whether it is hard or soft, new or old The variations in production of two different tubes at different times may naturally be still greater, and the chances of obtaining the same results with two different installations or at different times are almost minimal if we do not know exactly in each case the quality and the quantity of the rays absorbed The dose must be proportioned to the disease This rule applies to other diseases besides ringworm, and where more than one séance is necessary one should adopt Béclère's rule of causing to be absorbed at each séance the maximum quantity of rays compatible with integrity of the integument, and interpose between the different séances the minimum interval of time compatible with integrity of the integument Neoplasms and many other cutaneous lesions must be treated thus, but ringworm offers a simple problem inasmuch as the patients are more or less of a similar age, the lesions are situated on similar areas of the scalp and are the same in character and in depth The dose, too, necessary for successful treatment is less than that which will cause a radio dermatitis, so that it can be administered at a single séance, which is of course a great advantage when dealing with children

---

[1] This does not include the x rays.

[2] Bunch: *On Ringworm Infection in Man and Animals*, Brit. Med. Jour., vol. i., 1901, p. 323.

[3] Allan Jamieson: Edin. Med. Jour., June, 1900, p. 547.

The amount of dose necessary for the successful treatment of ringworm has been worked out by Sabouraud at the Hôpital Saint-Louis with the greatest care, and from personal observation covering several months I can assert that his treatment is simple and extremely effective The number of successful cases which I have seen is not only very considerable, but the relative proportion of successful to only partly successful or unsuccessful cases is certainly high Sabouraud has himself published results of treatment which show how greatly superior this method is in his hands to all the methods which he has employed before, and his description of this method and his conclusions are included in this paper The method is painless, the actual time necessary for the treatment is short, and the diseased hairs fall out at a definite interval after application of the x rays and are replaced after a certain time by a growth of healthy hair

The essential apparatus necessary is an electric current, constant or alternating, and a Crookes tube The electric energy for the production of the x rays can be derived from a static machine, a Ruhmkorff coil or a transformer, and the Crookes tube can be of almost any pattern or any age Sabouraud uses a static machine of ten plates driven by a three-quarter horse power dynamo[4] with a Béclère "spinter metre" interposed between it and the tube This latter modification warns the operator at any moment of an increase in resistance of the tube and enables him to make any necessary alterations The tube has an ingenious modification of Villars which enables it to be made "soft" at will To a lateral branch of the tube is attached the open end of a tube of platinum, the other end of which is closed When the resistance of the tube increases this tube of platinum is warmed by a Bunsen burner, gets red, becomes porous, and allows a little of the hydrogen of the flame to enter the tube If the tube contains too much hydrogen or is getting old (after about 50 hours of work) a second platinum tube of larger bore should be placed loosely round the first and heated, the tube will become very "hard" again In practice to render the tube which is being employed harder at will there is interposed a lateral derivation of the current—a resistance The relative hardness or softness of the tube is recorded by the radio-chromometer of Benoist, and in practice it is found that the resistance of the tube should correspond to the fourth division of the scale

Thus, by means of the accessory apparatus we know at any moment what is the degree of penetration of the x rays produced by the tube and are warned as soon as this changes and can immediately make the necessary alterations Only one measurement is still wanting It is that of the *quantity* of the x rays generated by the apparatus in a given time To measure this Holzknecht's pastilles have been employed These are composed of a mixture of alkaline salts and resin which slowly change in colour under the influence of the x rays One is placed in the path of the rays at a distance equal to that of the patient's skin From time to time the change in colour is compared to the standard scale, each of the 12 degrees of which is termed by Holzknecht *one unity H* Experience shows that the tint corresponding to 5 unities H on the scale must not be passed, at least at one sitting But these pastilles, although excellent, are a secret preparation and consequently are expensive To use them on a large scale would be a costly matter and Sabouraud has recently adopted the use of paper covered with an emulsion of platino cyanide of barium, which is cheap and can be employed several times It changes in tint when exposed to the rays and the tint which corresponds to five unities H is found and copied in water colour and kept at hand for reference when working It has an advantage over the pastilles in that it does not become darker when withdrawn from the rays, while the pastilles do, and that it regains its original colour again when removed from the rays and exposed to the light It is less sensitive, however, than the pastilles to the x rays and for estimations must be placed at about half the distance of the pastilles from the anti cathode[5] This must be borne in mind but does not otherwise create any difficulty

From the preceding the following rule is deduced To cure a patch of ringworm it must be exposed at a distance of 15 centimetres from the Crookes-Villars tube, the tube having a resistance corresponding to the fourth division of the radio-chromometer of Benoist, until the quantity of the x rays generated amounts to four and a half or five unities H of Holzknecht's scale By keeping to the above rule we can obtain a depilation pure and simple of the portion of scalp desired without complication of burns either trivial or grave—in a word, without accidents The operator and the healthy portions of the patient's scalp must be protected from the rays by inclosing the tube in an impermeable sheath perforated by apertures, one of which admits a metal tube corresponding to the size of the ringworm patch on the scalp. A scalp treated in this way shows no immediate result Towards the seventh day a scarcely perceptible erythema appears on the area which has been exposed to the rays but it may sometimes escape observation if it be not carefully looked for This erythema disappears after three or four days and is replaced by a pigmentation so little marked that it is necessary to search for it From the fifteenth day onwards the hairs fall out over all the area treated without any effort of traction and in a few days depilation is complete The extruded hairs are less glistening than normal and patients say that they look as if they had been scorched The hairs fall out because of the action of the rays on the hair papillæ, the function of which is paralysed for a time, but for a time only The old hair has been extruded by the time the new hair begins to grow but even when the new hair rapidly succeeds the old the two remain separated as a rule by a complete thickness of interposed epidermis

Thus it is possible that a hair which contains a parasite localised to the horny epithelium can be eliminated outside the skin by a physiological process without the new hair which is growing below being contaminated It is fortunate that this is so, for the action of the x rays is not fatal to the ringworm parasite and cultures made from the remnants of hairs in process of expulsion are still positive Re infection of the scalp is, therefore, easy and the greatest care is necessary to prevent such inoculation

The growth of the new hairs is slow. This is one of the inconveniences of the method but also one of the reasons of its success. The last débris of the diseased hair has long been extruded when the new hairs appear. The new growth as a rule becomes visible in the course of the seventh week after depilation, the tenth week after operation. Its date is a little variable but it never fails and hardly ever is later than 12 weeks after exposure to the x rays. The growth is always slow; in normal cases it is almost complete two months after its commencement. The treatment of a single patch of ringworm is simple. A single sitting is sufficient and the danger of re-infection or recurrence is minimal, but where a large proportion of the scalp is affected or there are numerous small lesions scattered over it a certain degree of difficulty arises. For to act upon all the upper surface of the scalp the tube would have to be placed some way off and as the time of exposure necessary increases as the square of the distance the immobility of a child could not be secured for a sufficient length of time. Moreover, oblique rays are weaker and less depilatory than vertical rays and they frequently lead to the development of pustular lesions round the irradiated area, no doubt owing to the staphylococci which are always present on the scalp ready to develop on any region which has undergone injury. Sabouraud goes further and states that oblique rays have a specific injurious action. Oblique rays should, therefore, be eliminated and where a large area of scalp has to be treated this is best done by dividing it up into several smaller square areas and treating each of them separately. Square areas are much more practicable than round, avoiding overlapping or the omission of small triangular patches where two or three circular areas adjoin, and they can easily be managed either by modifying the shape of the screen tubes or by inserting into the distal ends of the tubes diaphragms of lead in which square holes have been cut. The functional aperture of the screen tube is therefore now square, the areas which are treated can easily be mapped out, and no overlapping need occur at their lines of juncture.

---

[4] Vide Bunch: Sabouraud's Treatment of Ringworm by X Rays British Journal of Dermatology, July 1904

[5] 3 1 inches

Sabouraud has had six cases of x ray dermatitis in 2000 séances and these happened before estimation of the quantity of rays emitted by a tube in a given time was possible. In estimating this quantity it must always be remembered that it is much more dangerous to work with rays marking about 10° on the radio-chromometer than with those marking about 4°, since in the former case the rays are not only more penetrating but also more numerous. This has a bearing on the way in which tubes are to be employed. It has been pointed out that a Crookes tube after ten hours of service becomes coloured violet in the part exposed to the action of the x rays and after 30 hours this area begins to look smoky. This latter change is accompanied by a modification of the properties of the tube, in that it becomes more and more difficult to obtain from it the non-penetrating rays equivalent to 3°–4° on the radio-chromometer; when the attempt is made the tube does not illuminate properly and the anticathode hardly reddens, although from the same tube rays corresponding to 8°–10° can be obtained perfectly. These latter rays are equally capable of causing the hair to be shed, but when employing them it must be remembered that more rays are being employed in the same time and that the time necessary for depilation will only be half that necessary when rays corresponding to 4°–5° on the scale are made use of. But if this be remembered and the dosage accurately proportioned the effective life of the tube can be lengthened from about 60 to 150 hours. If, on the other hand, the dosage is inaccurate and the rays marking 8°–10° be continued for the half-hour necessary when rays equal to only 4° are used a well-marked dermatitis will occur about the tenth or twelfth day which at the best will not be more than an erythema and will disappear in a week. Even in this case, however, it will cause an alopecia lasting three or four months. If a more definite burn be produced the alopecia will inevitably be total, lasting, and complete.

Attention must also be paid to the danger of using too small a dose and having to repeat the dose. The first séance, if insufficient, will cause an imperfect fall of hair and if a second séance be given those hairs which survived the first time will fall out, but those which fell out as a result of the first treatment will not grow again. The possibility of such an alopecia resulting must be borne in mind and especially when there is a likelihood of two adjacent areas overlapping during treatment must it be remembered that such overlapping may cause a burn if the doses are maximal, even if an interval of several days be interposed between the applications of the rays. Such accidents can only be avoided by accurate measurement of the quantity of rays absorbed by the skin and accurate dosage but given satisfactory radiometry Sabouraud states that the recurrence of these accidents is impossible. Any want of success is due to other causes, such as restlessness of the child or forgetfulness on the part of the operator leaving an island of hairs which are difficult to see and which show up when the disease is cured everywhere else. Or there may be insufficient depilations at one or two points, leaving several diseased hairs which do not fall out, or reinoculation may take place during the course of treatment. But in spite of these possibilities the results are good. Before the time of radiotherapeutic treatment the average length of treatment of ringworm at the Saint-Louis Hospital was 18 months; now it is three and a half months. During the first six months of 1903 only 57 children were cured in the ringworm schools; during the first six months of 1904, 134 children were cured in the same schools; and among the cases successfully treated by the x rays were included over 100 which had resisted all other treatments. Such results have not been obtained in any other country and cannot be obtained by any other method of treatment. Moreover, these results could be considerably improved upon, even with the same apparatus and the same staff, if the children after having undergone x ray treatment were only kept in the ringworm schools until the hair had fallen out and then sent into the country until the new hair had grown. They would be non-infectious and would require only the most cursory medical supervision. When once the new crop of hair had grown again no trace of the disease would remain. In this way a large number of cases of ringworm could be cured in a short time at small cost and return to their ordinary school routine without the slightest danger of infecting other children.

Margaret-street, W.

SOME CASES OF URETHRAL STRICTURE COMPLICATED WITH A PROSTATIC FALSE ROUTE OR PASSAGE; WITH REMARKS.

BY REGINALD HARRISON, F.R.C.S. ENG.,
HUNTERIAN PROFESSOR OF SURGERY (1890–91), ROYAL COLLEGE OF SURGEONS OF ENGLAND; SURGEON TO ST. PETER'S HOSPITAL, LONDON.

THE records of surgery furnish some remarkable instances of this somewhat rare lesion where persons suffering from it have for some time led a more or less active life. I will take some illustrations of it connected with strictures in the deep urethra.

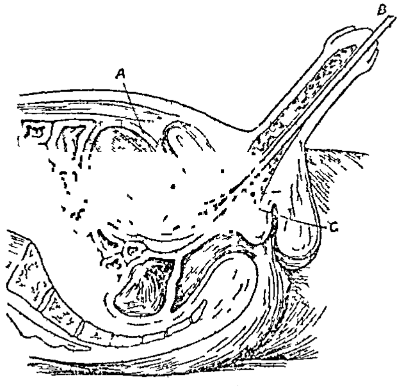
Some years ago a man was landed from a sailing ship in the following circumstances. He was a sailor, aged 40 years, and had suffered for many years from stricture. Three months before I saw him when at sea he broke his small elastic catheter in attempting to relieve an urgent attack of retention of urine. A silver instrument of a larger size was then passed for him by the captain of the ship with much force, pain, and bleeding. This process was subsequently repeated on several occasions during the voyage and the instrument was frequently retained for some hours at a time In the course of some weeks the man passed urine voluntarily in sufficient amount to keep himself comfortable and he was able to get about the ship but not to do duty. His general health, however, began to fail and on his arrival in port he was far advanced in renal disease. I passed a catheter for him but it was obvious that the instrument did not take a natural course, though several ounces of foul urine were withdrawn by it. The line of the catheter could be distinctly traced with the finger in the rectum. He died shortly after his arrival and a necropsy was made. There was a dense stricture in the deep urethra which would only admit a bristle and beneath it was a false passage through the prostate (which was not enlarged) one and a half inches in length which opened into the bladder above the gland and had done duty fairly well for the prostatic urethra.

For the two following cases I am indebted to my old friend the late Mr. W. Cadge of Norwich, whose work in connexion with stone and urinary disorders is so well known and appreciated. Mr. Cadge wrote to me in regard to the first: "This was a case where I made a post-mortem examination and the specimen is now in our hospital museum.

It was that of a man with a chronic stricture and perineal fistula, where a silver catheter had been forced in by a surgeon and the passage gradually dilated up to No 12 (English) The patient wore day and night a soft rubber catheter and he died after a few years of [illegible] After death it was found that the catheter [illegible] urethra at the front end of the stricture and [illegible] the proper [illegible] dder where, [illegible] lined with a smooth, shining membrane and answered the purpose of a catheter fairly well "

The other case was that of a man with an old stricture where a false passage had also been previously made Mr Cadge wrote "I used to pass a No 8 or 9 through the false passage but I felt sure it was a false passage and as he lived a long way from Norwich I put him in the hands of another surgeon nearer him who, with much care and pains got in a minute soft catheter through the stricture, kept it in, and in a fortnight he was able to use No 12 flexible and the patient, I believe, has never had any trouble since Mr Cadge further remarks "So far as my experience goes there is always one sign of a false passage present—viz , when a large catheter is passed and removed the false passage quickly or almost at once collapses and the patient cannot pass urine much better than before any instrument was used "

These two narratives were sent to me by Mr Cadge in response to the written particulars of the following case about which I was desirous of hearing from him It was that of a middle aged man whom I saw some time ago and who had an old tight traumatic or scar stricture and a false passage beneath it from the bulbo membranous urethra tunnelling the floor of the prostate and so entering his bladder through the trigone The lesion or false route seemed to correspond with the first case described in this paper of which I made a drawing (see illustration)



A, The prostate gland B, Catheter leaving the urethra in front of the stricture, passing through the prostate and entering the bladder C, Entrance of the stricture

For some time treatment had consisted in what was supposed to be dilatation of the stricture by the passing of metal bougies Later I was asked to see this patient and I also repeated this process but with the feeling that there was something wrong in the direction of the instrument Subsequently with a set of filiform bougies and fine "whips" I hit off the way through a long stricture immediately in front of the prostate and entered the bladder naturally It was clear then that there were two ways to the bladder through the prostate one by the natural course guarded by a very contracted stricture, and another which had been artificially made, so to speak, for occasions of great and recurring urgency How to close the one and to open the other was the point to determine The stricture was much too scar like and contractile to yield to dilatation, continuous or otherwise Guided by some experience in similar cases it appeared to me that this would be best secured by the combined operation of internal and external urethrotomy[1] This was effected in the following manner, which was planned to avoid adding unnecessarily *to the amount of scar tissue in relation with the urethra* By using a fine Holt's dilator introduced on a filiform guide [illegible] was stretched so as to permit of a Maisonneuve's [illegible] being passed by which the contraction was [illegible] this way I at once enlarged the very contracted urethra sufficiently to enable me to introduce a fair sized median grooved staff into the bladder Upon this a perineal section was performed and one of my full sized gum elastic drainage tubes was put into the bladder along what had been for some years a closely contracted and unused half inch or so of urethra The wound was closed with catgut sutures around the drainage tube which was secured in the ordinary way This patient made an excellent recovery and after many years' painful interruption again passes urine in a natural stream He takes the precaution of occasionally using a bougie for himself

In these cases where the deep urethra is involved in dense masses of cicatricial tissue, mainly the result of disease or injury, or both, and where perineal fistulæ are also present the combined operation is I believe, the surest treatment The possibility of such a complication existing as here described must not be entirely lost sight of in connexion with the symptoms presented in certain forms of deep urethral stricture In the instances which have come under my observation it was found possible to demonstrate that the normal canal though in an extremely contracted form, did exist Further, the cases narrated tend to show that with care and patience it is possible to restore the dimensions of the natural canal by dilatation or otherwise even after long periods of disuse and also permanently to obliterate the false route or passage

COLLES'S FRACTURE AND OTHER FRACTURES AND DISJUNCTIONS AT THE LOWER END OF THE RADIUS AND ULNA[2]

By ANDREW FULLERTON, M D R U I,
F R C.S, IREL ,
HONORARY ASSISTANT SURGEON TO THE ROYAL VICTORIA HOSPITAL, BELFAST ETC

THE term Colles's fracture ought to be confined to those fractures of the radius close to the wrist joint in which backward *displacement of the lower fragment occurs* It has, however, been loosely applied to all fractures in the vicinity of the joint The ordinary form of Colles's fracture is usually produced by falling on the hand in the three quarters pronated position and not, as is commonly stated, in the fully pronated position It is usually stated that the accident is most common in women of an advanced age In the series of 69 cases 54 per cent occurred between the ages of 30 and 50 years, and only 38 per cent after 50 years The largest number (17 cases) in any decade occurred between 30 and 40 years and 12 of these were males although taking all the cases together the numbers were 28 males and 29 females About 50 per cent of the women were over 50 years of age, while only 25 per cent of the men were over that age In the men, therefore 75 per cent of the fractures occurred before 50 years The side affected was noted in 47 cases 27 fractures were on the left side and 20 were on the right side In most of the cases the injury was situated within the last inch of the bone The series of sections of bone sawn from side to side and from before backwards shows that the compact tissue ceases about one inch from the tip of the styloid process on the outer side and about three eighths of an inch from its lower end on the inner side Behind, the compact layer descends to within about half an inch of the joint and in front a line or two further down

---

[1] THE LANCET June 11th, 1898 p 1611

[2] Abstract of a paper read at a meeting of the Ulster Medical Society held on Feb 2nd 1905 It was based upon a series of 69 cases [illegible] and splints

This accounts for the obliquity from above downwards and from without inwards, which is seen in a large number of the skiagrams. The presence of a spike of bone running up the shaft on the outer side is a marked feature in many cases. (Skiagrams were shown illustrating several unusual forms of fracture, including some of fracture of the radial styloid process alone extending into the joint on the inner side.) The ulna was implicated in over 50 per cent. of the cases. Skiagrams show that in fracture of the styloid process there is considerable variety among the results of treatment. In some this process unites again, in others it becomes thickened, in others it remains distinct, and in others it disappears altogether. In some of the cases fracture of the ulna at the same level as the fracture of the radius was found. Complete separation of the radius and the ulna with probable rupture of the triangular fibro-cartilage takes place in many cases. Fracture of the styloid process of the ulna alone may occur in injuries about the joint, as for instance, when the carpus is dislocated backwards.

The presence or absence of impaction was noted in 45 cases. In 12 there was marked impaction, two of these cases being fractures of both bones at the same level and in others there were probably some posterior impaction and some crushing of the fragments. In all these fractures a good result was obtained by manipulation and splints. Comminution as seen by skiagrams was present in five cases out of 47; it may have occurred in others but was not diagnosed either by skiagrams or by symptoms.

The displacement of the fragments and consequent deformity were carefully noted in all the cases and have been classified under the following three heads. 1. Those in which the lower radial fragment is displaced backwards, this being by far the most frequent form of the injury. 2. Those in which displacement of the lower fragment outwards is the most marked feature. In these cases the patient has probably fallen on the ulnar border of the hand. 3. Those in which forward displacement occurs, this being a very rare form of the injury. The description in text-books in which abduction of the hand is given as a sign of these fractures is open to great objection. In most cases the fingers are either in the normal position or are slightly flexed to the ulnar side, so that adduction of the fingers and radial displacement of the wrist would be a more suitable description. The cases in which there is narrowing of the interosseous space between the radius and ulna must be very rare; in several of those included in the series this space was actually widened in consequence of comminution of the lower fragment of the radius or separation of the radius from the ulna. In the cases with displacement to the radial side the wrist is broadened from side to side, suggesting a line of treatment different from that which is usually employed.

The complications that occurred in the series were as follows: fracture of the ulna at the same level, three cases; fracture of the styloid process of the ulna, 52 per cent.; rupture of the triangular fibro-cartilage allowing of separation of the radius from the ulna (comminution), five cases; injury to the median nerve, two cases; laceration of the tendon of the extensor secundi internodii pollicis by the ragged edge of the lower fragment, one case; fracture of the anatomical neck on the same side, one case; and fracture of a carpal bone (the scaphoid), one case.

In considering the treatment of these fractures it is essential to subdivide them according to the nature of the displacement. In dorsal displacement two splints ought to be applied, the anterior one not coming below the fracture and the posterior one being so padded that the hand is flexed to an angle of 45°. If there is impaction it must in all cases be first broken down, if possible, and the parts firmly pushed into position before the splints are applied. The recent suggestion that no attempt should be made to break down impaction or to employ splints is not to be recommended. The parts, however, ought not to be kept in splints for longer than a fortnight unless in very exceptional circumstances; the patients ought also to be visited every second day and encouraged to move their fingers. In the large majority of cases there was no stiffness of the wrist; when it occurs it is probably due to fracture into the joint or to injury of the carpal bones. In many instances the patients were able to return to their work in four weeks from the date of the accident. In those cases in which radial displacement is the principal deformity I have obtained good results by the use of a newly designed splint consisting of a piece of wood hollowed out to fit the ulnar border of the hand and forearm and having its metacarpal end made at a slight angle to the remainder of the splint. When in position it fits the forearm and ulnar border of the hand and the latter is neither abducted nor adducted. The radial fragment is drawn or pushed into its place and kept there by a pad which is securely fixed by means of a buckled strap passing round the lower end of the splint. The object aimed at is to keep the lower end of the radius close to the ulna by the pressure of the pad and strap. The splint is a little broader than the ulnar margin of the limb, so as to leave room for the circulation of the blood and lymph. Dorsal and palmar splints are useless for the correction of radial deformity.

The 11 disjunctions of the lower epiphysis of the radius all happened in boys at ages varying from seven to 18 years. At that time of life Colles's fracture is much rarer than disjunction of the epiphysis, but among the skiagrams there is one showing Colles's fracture in a boy, aged 11 years. The cause is indirect violence, such as falling from a height upon the outstretched hand or falling in the street on the palm or ulnar border of the hand. Fracture of the tip of the styloid process was seen in one of five skiagrams that were taken. In one case the epiphyses of both the radius and the ulna were displaced slightly inwards as well as backwards. There is reason to believe that the ulnar epiphysis frequently suffers as well as the radial one, for a few days later there is often a swelling at the spot, due probably to a loosening of the ulnar head and consequent epiphysitis. Permanent deformity or arrest of growth is quite exceptional in these cases.

Belfast.

A CASE OF ACUTE HÆMORRHAGIC PANCREATITIS; OPERATION; RECOVERY.

By T. C. LITLER JONES, F.R.C.S. ENG.,
ASSISTANT SURGEON TO THE LIVERPOOL ROYAL INFIRMARY.

A MARRIED woman, aged 26 years, was admitted into the Liverpool Royal Infirmary on Oct. 1st, 1904, with signs of intestinal obstruction. Her history was that except for constipation she had always been in the best of health. No history of indigestion, colic, or jaundice could be obtained. Her periods were quite regular, the last one starting six days before admission. She had had two healthy children. The patient stated that for the last year her constipation had been worse and that her bowels had not been opened more frequently than once a week and sometimes but once a fortnight. Early on the morning of Sept. 30th, whilst turning in bed to reach the baby, she was seized with a severe pain in the abdomen, as if "something had twisted." She had had no motion of the bowels for seven days but went to the closet and passed a small hard motion. The pain being now more severe she sent for a medical man who administered a small dose of morphine and an enema. During the day she had 12 enemata but passed nothing except a little flatus. She was sick ten times. On the day of admission she was sick twice but it was noticed that her abdomen was more distended. She reached hospital about midnight on Oct. 1st, nearly 46 hours after the "accident." Her condition on admission was as follows. She was a well-nourished, well-built woman, with an anxious expression, a dry mouth, and a very foul, furred tongue, which latter condition was out of all proportion to the severity of the case. Her abdomen was distended, there were signs of free fluid in the flanks, and there was a painful area in the epigastrium with localised swelling. Per rectum and per vaginam nothing abnormal was discovered. The pulse, which was 128, was feeble and fluttering. Her temperature was 96·2° F. It was obvious that some accident had occurred in her abdomen and the diagnosis was that of some gastric lesion, possibly perforated gastric ulcer.

The abdomen was opened in the middle line above the umbilicus and on dividing the peritoneum there at once issued a large quantity of bright blood mixed with serum. Probably three pints of free fluid were in the peritoneal cavity. The intestines were only moderately distended. Although her history negatived a ruptured extra-uterine pregnancy I examined the pelvic contents first and finding nothing abnormal proceeded to investigate the condition of the other abdominal viscera. Seeing at the entrance to the lesser sac of the peritoneum fat necrosis I made an opening through the gastro-colic omentum and found the affected organ. The pancreas, which was about three times its normal size, was discoloured, œdematous, and in places hæmorrhagic. There was no bleeding at the time of the operation from the pancreas. I now mopped out from the abdomen the blood and serum and removed from the omentum a small piece of fat for microscopical diagnosis. Having packed the area around the pancreas with gauze I incised that organ longitudinally. Introducing my finger I searched for an obstruction such as a stone or an abscess but found nothing that would account for the condition. My finger gave me the impression of entering a dilated space, which space I packed with sterilised gauze. This packing arrested the hæmorrhage which was never as profuse as I had expected and which at all times could be controlled by moderate pressure. The end of the gauze packing was brought out of the abdomen, the wound was closed in its lower two-thirds, and the patient was returned to bed, having borne the operation well. The packing was cautiously removed in 36 hours' time, when a discharge of clear fluid began and continued. This was pancreatic juice and it soon caused trouble at the upper part of the incision, the lower two-thirds of the wound healing by first intention. Apart from an *abscess which formed in the abdominal wall, owing*, perhaps, to the tube being taken out a little too soon, the patient made an uninterrupted recovery, leaving the hospital quite well, with the wound firmly healed, on Dec. 10th. For the first three weeks after the operation fat-containing food was withheld as much as possible. Her urine was most carefully examined on two separate occasions and nothing in the nature of the crystals described by Cammidge could be obtained. A motion which was passed naturally on the day following the operation was apparently normal and no history of any previous alteration in the appearance of her evacuations could be elicited.

With regard to the pathology of the condition nothing very definite is known. Mayo Robson and Barling emphasise the association of this condition with gall-stones; knowing this I looked carefully for any sign of such at the operation. Halsted, arguing from a necropsy after an unsuccessful operation for acute hæmorrhagic pancreatitis, where the duodenal orifice of the duct was obstructed by a minute calculus, suggested that the bile entered the pancreatic duct by retrojection from the common duct. Opie performed experiments to test this opinion and his conclusions are that the necrosis of the parenchymatous cells and the hæmorrhage represent the primary action of the bile, and that inflammatory action rapidly follows. Mayo Robson asserts that the immediate cause of the various forms of pancreatitis is bacterial infection. Heaton showed specimens of a very similar case recently.[1] In his case the ducts were patent and the microscopical sections showed acute inflammatory changes in the gland and areas of blood extravasation. Deaver, in the American *Medical News* of March 5th, 1904, strongly advises early operation as giving the best results. He recommends free drainage to check progressive necrosis of the pancreatic cells due to the action of the ferment and says that a tense œdematous condition of the organ, without marked involvement of the peripancreatic tissues, calls for an incision in its long axis. The points of interest in this case, apart from its rarity, are the age of the patient, the extremely foul, furred tongue, the absence of any known cause, the difficulty in diagnosis, and the uncertainty of treatment.

Liverpool.

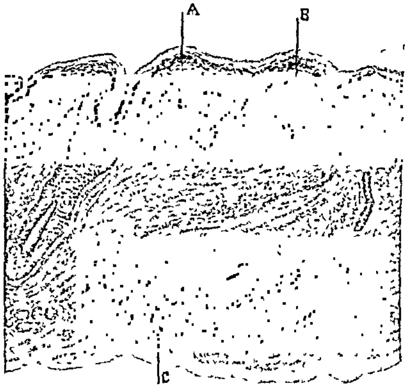
THE HISTO-PATHOLOGY OF SEBORRHŒA, SEBORRHŒIC DERMATITIS, AND PSORIASIS.

BY R. W. BRIMACOMBE, M.D. BRUX.,
ASSISTANT PATHOLOGIST, ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN.

THAT there is a connecting link between seborrhœa, seborrhœic dermatitis, and psoriasis has been recognised by dermatologists, although as far as I am aware only from a clinical point of view. It is my intention in this paper to demonstrate their connexion as seen under the microscope.

I shall, however, adhere to Sabouraud's definition of the word seborrhœa, "flux of sebum," and consider that seborrhœa should be restricted only to those cases in which there is a sebaceous hypersecretion. In all such cases there is hypertrophy of the sebaceous glands. That seborrhœa persists throughout life without any other change is evident, that a dermatitis is liable to develop is certain, and consequently we have seborrhœic dermatitis. In these cases, as I shall show, the secretion is mainly sudoriparous, as the sebaceous glands have become atrophied. Taking a section of a papule at this stage the most striking feature in a microscopical specimen is the partial and in most cases total disappearance of the sebaceous glands. There are, however, other important changes. The horny layer shows slight increase of horny cells—that is to say, increase in depth of layer—but here and there are small areas showing a greater development of *horny cells (piling up) in which are included* a few deeply stained leucocytes (polynucleated cells) (A). This is due to the increased capillary circulation in the cutis pushing up or flattening out the epithelial layers. The epithelial layers themselves are slightly increased, due to a swelling of the epithelial cells and dilatation of the lymph spaces between them. Where the narrowing of the epidermis has taken place the leucocytes pass from the capillary circulation through the dilated lymph *spaces into the horny layer and it is here the more* highly developed horny cells form a kind of roof to these leucocytes (B). At this same point the stratum mucosum cells are flattened, the nuclei of which are slightly swollen, and the protoplasm of the cell does not take the stain so deeply as that of the normal cell. The capillary circulation throughout is increased but it is especially at this shrinking of the epidermis that the greatest development takes place. The endothelial cells are swollen and an inflammatory exudation takes place in which are seen the mononucleated and polynucleated cells. This thinning of the epidermis and increase of the horny cells naturally suggest to one the starting point of psoriasis. The changes which have taken place in the cutis, apart from the atrophy of the sebaceous glands previously mentioned, are the hypertrophy of the sweat glands with wideness of lumen and swelling of epithelium (C). (Fig. 1.) I should, however, mention that in some very few cases there is only marked atrophy of the sebaceous glands and in these the cubical cells forming the wall of the gland and the sebaceous cells are very wasted. Where a papule appears over a hair follicle—more often it does not—the follicle becomes dilated and filled out with horny material only. Here, then, it seems to me we have a *definite cause for seborrhœic dermatitis* and can dispense with the micro-organism theory put forward by continental dermatologists and seconded by the Americans. That micro-organisms are present is evident but they are due to secondary inoculation and are readily

FIG. 1.



Section of seborrhœic dermatitis papule.

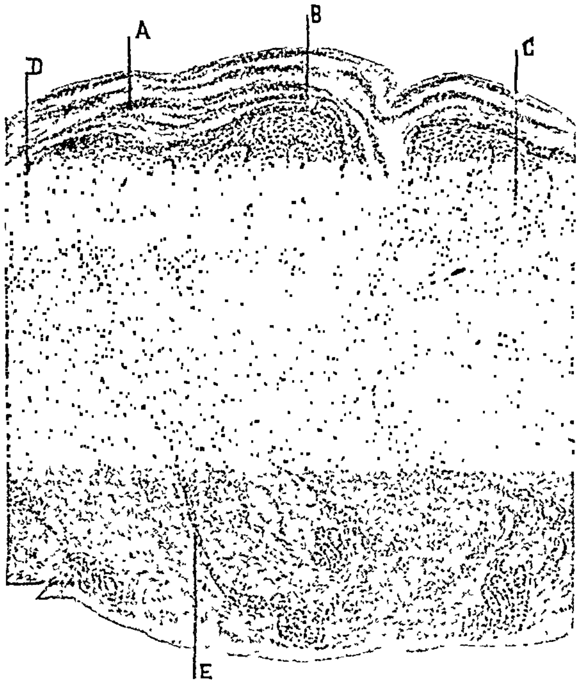
---

[1] Brit. Med. Jour., Dec. 17th, 1904.

demonstrated in healthy subjects. Surely if the coccus is the cause of seborrhœic dermatitis we ought to be able to find it in the deeper layers of the skin and not only in the horny layer. The sebaceous glands having failed the sweat glands take on an extra amount of work and become hypertrophied in the attempt to keep the skin normally lubricated. This they fail to do and the amount of secretion being altered accounts for the dermatitis. That the secretion at this stage is a sudoriparous one bears out Unna's theory that he has found fat in the coil glands and believes the coil glands to be the source of most of the fatty secretion characteristic of eczema seborrhœicum. Fat globules, however, are readily demonstrated in the normal coil glands.

Clinically, cases of seborrhœic dermatitis and psoriasis mixed are numerous, also cases of seborrhœic dermatitis passing on to psoriasis, but microscopically the connexion between the two so-called diseases becomes evident. In psoriasis the horny layer is well developed, the cells showing well-marked nuclei on account of the cell being softer and not having acquired that characteristic horny condition as seen normally. That is to say, the process of cornification is incomplete and is due to the rapid formation of scales. Between the horny cells are seen some atrophied wandering cells—polynucleated leucocytes (A). The stratum granulosum cells become flattened without well-marked granulation (B) and the stratum mucosum cells are swollen, with dilatation of the lymph spaces between them. The inter-papillary cone (C) shows high development and is pushed down into the cutis. The papillæ (D) are widened, the connective tissue œdematous and staining badly. (Fig. 2.)

FIG. 2.



Section of patch of psoriasis.

The capillaries in these spaces are dilated and increased with surrounding leucocytosis. Owing to the development of the capillaries and consequent pressure the whole epidermis becomes thinned and the epithelial cells flattened out, only one or two layers of the stratum mucosum remaining instead of the eight or ten normally. This condition, together with the dilated lymph spaces, accounts for the leucocytes wandering amongst the horny cells and the well-known clinical sign of a readily bleeding surface after removal of the scale with the finger-nail.

As in seborrhœic dermatitis, so in psoriasis the cutis shows the most important changes. There is a great increase of connective tissue with swollen bundles and *proliferation of connective tissue cells. The lymphatics and* blood-vessels are dilated with infiltration of leucocytes around their walls. The sebaceous glands as a rule are absent but occasionally they are present in a very atrophic state. The most noticeable feature, however, is the atrophic condition of the sweat glands and duct. I do not mean to infer that they are completely atrophied or useless. All stages are seen both in the duct and the glands, from the swollen epithelium in one part to the atrophic condition of the cells in another and their total disappearance elsewhere (E). Where the swollen epithelial cells are present there is wideness of the lumen of both duct and glands and where atrophic cells are present the lumen is narrowed and in some cases closed up by the approximation of the two atrophic cellular layers. The duct of the sweat glands is increased in length, having to accommodate itself to the greater increase of cutis and the lengthened duct is probably due to the pressure on each side of it of the œdematous connective tissue. The atrophy is also to be explained in a great measure by disuse. In old-standing cases of psoriasis the œdema of the connective tissue has disappeared and the depth of the cutis more closely approximates that of the normal. It is also in these cases that the atrophic condition of the sweat glands and duct is most marked. The natural secretions of the skin failing, the accompanying inflammation must be looked upon as a *secondary process* and not as stated by Unna and Elliott "to be a primary affection and not a disturbance in secretion."

Cavendish-square, W.

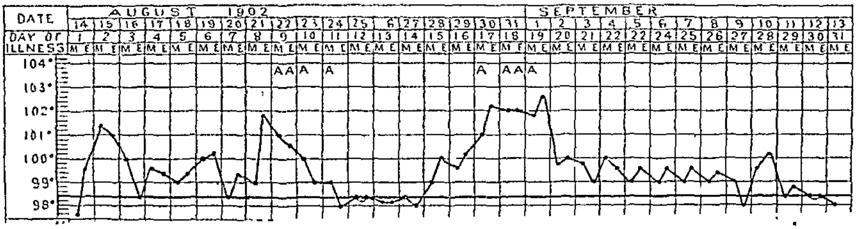
A CASE OF ENDOCARDITIS WITH PERICARDITIS FOLLOWING SCARLET FEVER; TREATMENT BY ANTISTREPTOCOCCIC SERUM; RECOVERY.

BY ALFRED R. SPENCER, M.B. LOND., M.R.C.S. ENG., L.R.C.P. LOND.

THE following case is of interest for two reasons—first, because antistreptococcic serum, although of proved efficiency in other conditions, is still on its trial in cases of endocarditis of malignant type, and secondly, because endocarditis and pericarditis are not common sequelæ of scarlet fever.

The patient, who was a boy, aged five years, was taken to the South-Western Hospital of the Metropolitan Asylums Board on June 22nd, 1902, suffering from scarlet fever. He was transferred to the Board's Northern Hospital at Winchmore-hill, N., as a convalescent on July 22nd. While at the South-Western Hospital he had otorrhœa of both ears early in July, but on arrival at the Northern Hospital both discharges had ceased. He had never had rheumatism but had always been a weakly child. There was cardiac trouble on the father's side and the mother had had rheumatic fever three times, her last attack being shortly previous to the patient's birth. After his transfer on July 22nd the patient had been up and about up to August 13th. His temperature on the night of August 13th was found to be 101° F. and it continued so till the early morning of the 14th, dropping to 97·6° later in that day. In the evening it was again 101°. The patient was now definitely ill, restless, and complaining of slight pain behind the right ear but chiefly of pain on the right side of the chest; he had also slight cough. His respirations were rapid, being 48 per minute in the evening; at night they were more rapid still—namely, 60 per minute—and he was in great pain and distress. On examination the fauces were found to be reddened; some loose mucous exudate was also seen on them and on the posterior pharyngeal wall. The chest was fairly covered and was of fair shape and size; there was no obvious bulging of the præcordium or of the bases of the lungs. Cardiac pulsation was seen and felt over the cardiac area in the fourth and fifth intercostal spaces of the left side outwards as far as the nipple line. The impulse was forcible but showed some irregularity in both force and rhythm. There was no cardiac thrill. No pericardial or pleural friction was felt. There was some impairment of the movement of the left base in the axillary line. The lungs showed signs of pleurisy and slight patchy consolidation at the left base in the axillary line and in both bases posteriorly. The area of maximum intensity of the cardiac impulse was just internal to the nipple line in the fifth space. The right and upper limits of dulness were normal; the left limit was just internal to the nipple line. Auscultation of the heart revealed at the apex a well-marked somewhat rough systolic murmur which was heard over the area of maximum intensity of impulse and was localised to this area. Also, localised to this area a pericardial rub was heard at the end of the systolic murmur and throughout the diastole; this rub was confined to the region of the apex. Over the pulmonary and tricuspid areas the heart sounds were embryonic in character. At the aortic cartilage the first sound was weak.

On August 15th his temperature was 101° and his pulse quickened to 156 per minute, from 130 on the day before. On the 16th there was a morning fall of temperature. The cardiac impulse was seen and felt half an inch external to the nipple line. No pericardial sounds were heard. On the 18th the cardiac impulse was three-quarters of an inch external to the nipple line but the outer limit of the cardiac dulness was one inch external to it, and the upper limit of the dulness reached the lower border of the second rib. On the 20th pulsation could be seen in the third, fourth, and fifth intercostal spaces and percussion revealed dulness in the first and second spaces close to the sternum. The skin showed a raised confluent erythema in irregular patches, gyrate, scattered on the trunk and more widely scattered on the limbs. There was none on the face and there was no irritation. Later in the day there were diarrhœa and also vomiting of the contents of the stomach. On the 21st the diarrhœa and vomiting continued; at times there was some irregular sweating; the facial expression was anxious and frightened as though the patient were fearful of some impending calamity and there was much respiratory and cardiac distress. The eruption continued to spread; it was still gyrate; it was paler centrally than at the periphery, where there was a well-marked border, dusky purple-red in colour. On the 22nd the patient was prostrate in bed, apparently unconscious of his surroundings and possessing very little control of the sphincters. His tongue was dry; the teeth and lips were covered with sordes; the pulse was flickering; his temperature was 101° at 10 A.M. There was profuse sweating at irregular intervals. The eruption had spread so that the trunk was almost covered. At 1.20 P.M. ten cubic centimetres of antistreptococcic serum were injected hypodermically into the loose tissue of the flanks. His temperature at 6 P.M. rose to 102·2° and at 10 P.M. dropped to 100·6°. Ten more cubic centimetres of serum were given. On the 23rd the patient was much better, the rash was fainter, and the sweating was less copious. Ten cubic centimetres of serum were given at 12 noon. His temperature at 10 P.M. was 99°. On the 24th the rash was almost gone. There was obvious bulging of the præcordium and pulsation was diffuse in the third, fourth, and fifth intercostal spaces. The cardiac impulse was three-quarters of an inch external to the nipple line but the outer limit of the cardiac dulness extended outwards to the anterior axillary line. The results of auscultation were as follows. Succeeding the systolic murmur at the apex there was a diastolic murmur replacing the second sound. At the base, over both pulmonary and aortic cartilages, there were soft systolic murmurs followed by a sharp second sound. There was also a shuffling pericardial friction sound, altering in the time of its occurrence with reference to the cardiac cycle. There was no enlargement of the liver or spleen.



On the 25th and 26th the temperature did not reach above 99°. On the 28th it rose to 100°. There was on the abdominal wall an irregular papular rash, light pink in colour, fading on pressure, quite symmetrical on the two sides, and bounded laterally by the nipple lines; towards Poupart's ligament it became a raised erythema in large scattered patches, darker in colour than above described, and its colour was more persistent on pressure. This rash did not extend below Poupart's ligament and on the next day it had almost disappeared. On the 30th bulging of the præcordium was much more marked and dulness extended over the inner ends of the first and second intercostal spaces on the left side for one and a half inches. The liver dulness extended a finger's breadth below the right costal margin. Injections of serum were recommenced as shown on the accompanying chart. At night the patient was very restless and was observed to lie chiefly on his left side but he did not complain of pain. The respirations varied much in amplitude and frequency, at times assuming a Cheyne-Stokes character; the diaphragm moved normally. On the 31st there was some reappearance of the rash; the inguinal glands were enlarged and tender. The pulse-rate was 156 and the temperature was 102·4°.

On Sept. 1st pulsation was seen over the whole of the præcordium and in the left mid-axillary line in the fourth and fifth intercostal spaces. Dulness extended outwards to the left mid-axillary line below and reached in the third space to the nipple line. A to-and-fro pericardial rub was heard at the inner ends of the second, third and fourth spaces and over the sternum adjoining. At the base of the left lung behind and in the axilla there were signs of compression of the lung. The axillary glands were slightly swollen, those on the left side being tender as well. On the 3rd the dulness on the right side of the heart was extending in the lower spaces. On the 6th signs of lung compression were well marked at the left angle of the scapula. Over the aortic cartilage there was a systolic murmur conducted up into the carotid arteries and heard over the subclavian. On the 7th two large irregular patches of erythema appeared on the skin of the abdominal wall with a few faint spots on the thighs. There was pain over the left hypochondrium and friction fremitus was very well felt over the inner ends of the intercostal spaces, especially close to the sternum. The patient was very wasted and very pale. On the 8th the bulging over the præcordial area was a marked feature at this stage, as also the pulsation visible over the whole area, somewhat undulating in character. On the 11th auscultation at the apex revealed a whistling systolic murmur, preceded by a rough, loud, harsh presystolic murmur. Over the aortic cartilage there was a well-marked to-and-fro murmur; capillary pulsation was not obtained.

By Sept. 22nd the patient was assimilating food well and was not wasting so much. By the 29th the fluid in the pericardium was practically absorbed; there were signs of pericardial adhesion and of much dilatation of both left cardiac chambers. The aortic murmurs had cleared up and the pulmonary sounds were then embryonic in character.

On Oct. 20th the patient's appetite was good and he was gaining strength and flesh rapidly. The cardiac impulse extended outwards to the anterior axillary line in the sixth left intercostal space and did not change as the patient changed his posture. In the fifth space, internal to the position of the impulse, there was some systolic recession. There was some impairment of the percussion note at the inner ends of the first and second left spaces for an inch or more. The cardiac dulness on the right side did not extend across the middle line. On auscultation both sounds at the apex were found to be replaced by murmurs. The systolic murmur was rough and loud; it was heard best at the point of impulse but was conducted out to the axilla, and was heard also over the whole of the cardiac area and over the whole of the back of the chest. The diastolic murmur was very soft, blowing, and quite localised to the apex and neighbourhood.

Summarising the general features of the case it may be remarked that the patient did not suffer from rheumatism or joint trouble. A systolic murmur localised to the apex may occur in patients convalescent from scarlet fever; this murmur disappears later and is probably hæmic in origin or arises in connexion with the slight cardiac dilatation so often met with in these convalescent cases. It is evident that in the case above described the mitral valve was very definitely affected and permanently impaired. The aortic murmurs, which subsequently cleared up, may have been due to pressure of exudation outside the aorta causing functional derangement of valvular action, and the return to normal valvular action may have been consequent on subsidence of the exudation; at the time of recurrence, however, it was feared that the aortic valve was permanently damaged structurally. The occurrence of irregular temperature with a cardiac murmur, accompanied by vomiting, diarrhœa, rash, and sweating, rendered the diagnosis of early infective endocarditis tolerably certain. The grave constitutional symptoms observed on August 22nd pointed to a profound toxæmic condition, with probable involvement of nerve centres.

With regard to the use of serum treatment in cases of infective endocarditis I find that up to the date of this patient's illness eight instances of the use of antistreptococcic serum in such cases had been published in THE LANCET and opinion was divided as to its efficacy; of the eight then reported cases four had recovered and four had died.

From a study of these published observations it is clear (1) that the earlier the treatment is begun the better is the hope of recovery; (2) that it is undesirable to wait for a positive confirmation of the diagnosis, such as embolism or infarct, before beginning treatment; and (3) that the size of dose should be regulated, not by the age of the patient but by the gravity of his or her condition.

The accompanying temperature chart is a *résumé* of a four-hourly chart; it shows the temperatures at 10 A.M. and 10 P.M. but does not show the daily remissions as clearly as they occur on the four-hourly chart. The improvement with serum in each case is apparent.

After I had written the above Dr. Cyril Ogle published in THE LANCET of March 14th, 1903, p. 720, a *résumé* of 19 recorded cases of malignant endocarditis treated with the serum in which an attempt was made to identify the organisms present. Of these some were mixed infections; in seven of the cases streptococci had been found in the blood; of these seven three cases of recovery were reported with only one recovery in the case of the others. Dr. Ogle's conclusions were (1) that though, taking all cases of septicæmia treated with the serum, there was a certain chance of recovery in most, yet in malignant endocarditis the chances were less favourable on account of the colony of cocci involved in the vegetations being in constant contact with the blood stream; (2) that the occurrence of staphylococci, or a mixed infection, was frequent; and (3) that if examination of the blood prove negative then it would be prudent to inject sera "anti" to both varieties of organism.

With regard to the nature of the micro-organism present in acute cardiac conditions in infectious disease it may be interesting to state that in the Western Hospital of the Metropolitan Asylums Board at Fulham I had under my care a case of acute pericarditis coming on early in the acute stage of scarlet fever; the illness proved rapidly fatal, and cultivation of the blood taken before death gave a copious pure culture of staphylococci.

I am indebted to Mr. F. N. Hume and Mr. R. M. Bruce, medical superintendents of the Northern and Western Hospitals respectively, for their permission to publish the above.

FIFTEENTH INTERNATIONAL CONGRESS OF MEDICINE AT LISBON.—Dr. R. Saundby has accepted the post of reporter in the Section of Medicine on the subject of the Treatment of Cirrhosis of the Liver.

TRAUMATIC LUMBAGO.

BY FRANK ROMER, M.R.C.S. ENG., L.R.C.P. LOND.

BY traumatic lumbago I mean a condition in which pain and stiffness in the lumbar region caused by injury persist long after the immediate and acute effect has passed away. Many such cases have come to my notice and they have shown good results from treatment based on the assumption that the condition is due to some adhesions in the muscular or tendinous structures of the lumbar region.

It is obvious that absolute proof of the exact lesion in cases of this kind is not to be found. In the first place, if the subjects of this complaint come under treatment they are fortunately very unlikely to be the objects of a post-mortem examination at all soon after. As a matter of fact, I have never had an opportunity of investigating post mortem the lumbar region of any person who had recently suffered from, or been treated for, traumatic lumbago. In the second place, the damage, whatever its exact nature, is deeply seated in a part of the body where muscular and tendinous fibres are thickly superimposed. It is not possible, therefore, to be certain of bands or adhesions in the same way that can be done in the case of a knee- or elbow-joint, for instance, or between viscera in the abdomen. The nature of the accident, however, that produces the condition and the results of treatment leave in my own mind little doubt that the causative lesion is of the nature of adhesions, and possibly adhesions affecting the bony structure of the sacro-iliac joint, as well as neighbouring tendons.

The history of these cases generally tells of some definite, though frequently slight, sprain or rick of the back, necessitating, perhaps, but a few days' rest for apparent recovery. Instead, however, of perfect recovery the pain, though rarely severe, does not quite disappear and as time goes on becomes more persistent. Lumbar stiffness increases and a condition arises similar to that of chronic lumbago. In the majority of these cases pain, though present in the whole lumbar region, is especially referred to one defined spot in particular. Treatment is then usually instituted on the supposition that ordinary lumbago is the condition to be dealt with. Such treatment is of little or no use in the cases to which I am referring.

On examination the lumbar muscles generally are found to be wasted, whilst on the affected side they are usually also rigid and contracted. It may be assumed that it is here that some matting of the muscles or adhesions amongst the deeper tendons exist. In making this examination my first care is to exclude the possibility of the case being one of early spinal caries. This being determined treatment aims at stretching the contracted muscles and rupturing the adhesions which are deemed to be present. An anæsthetic is given both for the prevention of pain and to insure complete muscular relaxation and absolute freedom in manipulation. The patient is placed on his back, the leg on the sound side is flexed at the knee, and the thigh is flexed on the body till the knee touches the chest wall. It is then brought back to the extended position. The leg on the affected side is now put through the same movements and comparison can be made as to the difference in resistance. Almost invariably it will be found that the leg of the affected side is not brought up with the same ease as was the other. Both legs are now brought up together and both knees should be kept pressed against the chest for about a minute. The legs are now brought down again flat on the bed and the patient is raised to a sitting posture. The operator places one hand firmly over the affected lumbar region, whilst with the other he thrusts the patient back towards the bed. The hand in the small of the back causes the part against which it is placed to be extended. By this procedure the lumbar portion of the spinal column is put through flexion and extension as the patient is pressed forwards and backwards. As a rule little pain is experienced after the manipulation and there is no need to enforce rest once the effects of the anæsthetic have passed off.

The after-treatment is directed towards the maintenance of movement, for which purpose it is advisable to have the lumbar and gluteal muscles skilfully shampooed within six hours of the operation. In the course of a few days exercises graduated by means of pulleys and weights should be commenced in addition to the rubbing. These serve both to restore the muscle waste and to keep the part supple. Later swimming is the finest of all exercises for the same purpose. With the increase of strength there are freer movement and decrease of pain. I append brief notes of the following cases as examples of traumatic lumbago.

I may say that Case 1 illustrates remarkably well the kind of accident which is liable to cause the damage that results in traumatic lumbago. The patient, a strongly built young man, was returning from the hunting field. He was leaning sideways to stop a swinging gate when his horse suddenly swerved. The twist suddenly given to his back in the effort to retain his seat caused immediate sickening pain in the lumbar region. The dull pain that subsequently persisted was well localised to a small portion of the left lumbar region. All treatment failed till the proceedings above described were carried out. The result was complete recovery.

CASE 1.—The patient, a male, aged 28 years, sprained and twisted the left side of the back eight months previously. He rested a fortnight absolutely but had never recovered lifting power. There was dull pain in the lumbar region. For the past two months this had been worse and he had laid up again. This gave no improvement. He had tried treatment for rheumatism. He was operated on as described above and also shampooed and exercised afterwards. In two months' time he was able to play cricket and to ride free from pain. (He has remained well for six years.)

CASE 2.—The patient, a male, six months previously sprained the right sacro-iliac region lifting his wife who was ill. After this he spared it as much as possible. It had been painful off and on ever since, more continuously for the past few months. No treatment but rest had been tried. He was operated on as described above and shampooed and exercised. He did well. I saw this patient recently. He has been sound since the treatment and has hunted regularly.

[illegible] months [illegible]o treat- [illegible]ill four [illegible] treated [illegible] and he [illegible]l, espe- [illegible] to ride or to row. When I saw this patient the lumbar muscles were very wasted and contracted, especially on the left side. I operated on him in the manner described. Afterwards he was shampooed and exercised. Marked improvement took place within ten days. When last seen he was able to ride and to walk about freely with very little pain.

CASE 4.—The patient, a male, sprained his back wrestling three years previously. He rested. Again at football three months previously he repeated the injury. Absolute rest was instituted. Pain on attempting to lift anything from the ground, especially on the left side, persisted in spite of prolonged rest. The left lumbar muscles were rigid and contracted. He was treated as the preceding case. He did very well and when last seen was entirely free from pain with perfect movement.

CASE 5.—The patient, a male, four years previously "ricked the back." Eight months previously he ricked it again. He kept quiet for a few days. Pain had been constant of late. Riding was painful and lifting was painful, with loss of power, especially on the left side. No treatment was tried but rest. The lumbar muscles on the left side were rigid. Movement was impaired. Operation was carried out as described above with shampooing and exercising. He was practically sound in three weeks. He is now able to bend and to lift with ease.

CASE 6.—The patient, a male, in May, 1903, on moving quickly experienced sudden and acute pain in the lumbar region, entirely incapacitating him. He was treated for lumbago. In the following August he was worse. Rest and rheumatic treatment were tried. Massage improved the condition. On attempting exercises three months previously he became much worse. He tried Droitwich for six weeks with heat baths. There was no improvement. The patient had been an athlete and was powerfully built. In November, 1904, he was unable to stand straight and sitting any length of time caused lumbar pain. There was considerable lateral lumbar curvature and he was doubled up, as in extreme old age. The lumbar muscles were so contracted that movement was nearly impossible. I operated as in the previous cases. Shampooing and exercises followed. He began to show immediate improvement. He was able to lace his boots within a week and within a month to touch his toes without bending the knees. He then went to the country to carry on treatment for himself but returned in two months, having strained himself in the right lumbar region. I stopped the exercises and ordered him to be shampooed only. Gradual improvement followed. Pain is now (January, 1905) practically absent, the curvature has disappeared, and movement is nearly perfect. This case was particularly interesting from the extraordinary amount of deformity present.

Cases 1 and 2 I saw with my partner, Dr. Wharton P. Hood, who first advocated this treatment and it is with his permission that I publish them.

Seymour-street, W.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A NEW METHOD OF ACCURATELY EXAMINING THE HYMEN IN MEDICO-LEGAL CASES.

By J. LIVINGSTONE LOUDON, M.D. GLASG., D.P.H.

IN all cases of alleged rape it is of the utmost importance that the condition of the hymen should be ascertained and if it has sustained any injury the full extent, nature, and position of it accurately estimated. Of course, it is only in cases where the victim has up to the time of assault been a virgin that the hymen will most likely show traces of injury and the younger the woman the more difficulty there is in making an examination which is at the same time painless and yet thorough.

The following method of thoroughly exposing the hymen I have frequently found most effectual; it is, moreover, simple, easily managed, and, if done carefully, painless. The patient being in the lithotomy position and swabs from the vagina (for examination for semen) having been taken the parts are freely treated with a 20 per cent. solution of cocaine, possible toxic effects where there are large raw surfaces being kept in mind. An ordinary soft red rubber catheter is then taken and over its point for about one inch or one and a half inches there is placed an ordinary indiarubber condom which is tightly bound into the stem of the catheter by a few turns of thread. There is thus improvised an instrument closely resembling one which used to be employed for arresting hæmorrhage in cases of epistaxis, the armed catheter being placed in the nose and the point inflated and so caused either to press on the bleeding point or plug the nostrils. This arrangement is gently passed into the vagina; the point is then expanded either by inflation or by injecting a small quantity of warm water; this done the catheter is clamped. There now is inside the hymen what may be termed a miniature Champetier de Ribes bag and by making *very gentle* traction on the catheter the hymen is put slightly on the stretch and bulged from within. In this way the whole hymeneal margin is fully exposed to view, so that any interruption in its integrity is at once detected, however slight it may be. In very young girls this method will be found particularly useful, as the hymen is very inaccessible then.

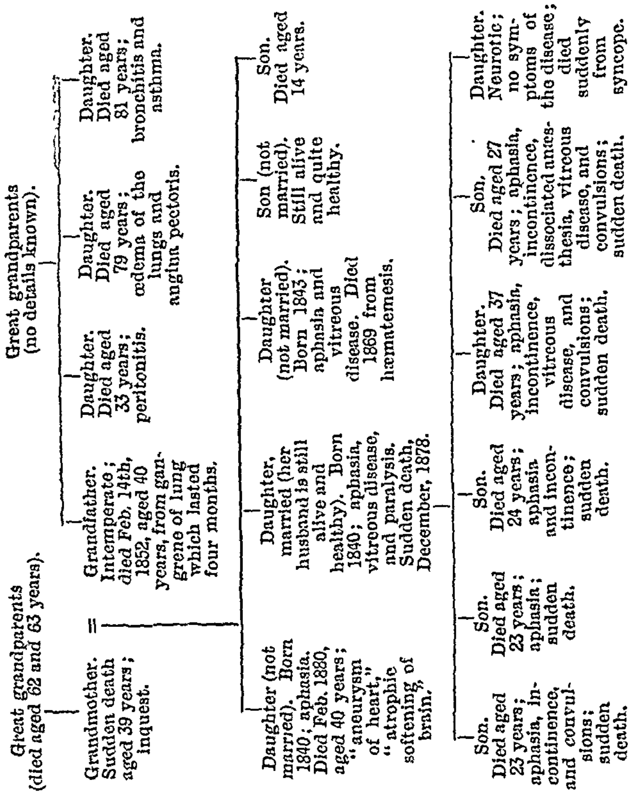
Hamilton, Lanarkshire.

A NOTE ON A CASE OF HEREDITARY APHASIA.

By W. GREAM STONE, M.A., M.D. OXON., F.R.C.S. ENG.

THE following case, for the details of which I am indebted to Mr. R. H. Jocelyn Swan, is reported to complete a series of cases published in the autumn number of *Brain*, 1902. The patient was the last survivor of a family of six, five of whom had suffered and died from this disease, which also affected their mother and two of her sisters. The main clinical features of the disease, which does not appear to [illegible] to adult life, are the [illegible] aphasia with loss of power on the right [illegible], (2) incontinence of urine, probably due to analgesia of the bladder wall; (3) gradually increasing opacities in the vitreous humour of the eyes; (4) loss or diminution of the senses by which pain and temperature are appreciated; (5) epileptiform convulsions; and (6) sudden death preceded by complete unconsciousness. The pathology of the disease in the only case in which there was an opportunity of examining the organs after death proved to be a spinal leptomeningitis which extended from below upwards until the cerebral meninges were affected in a like manner; the posterior columns of the cord and the posterior nerve roots showed well-marked degeneration.

The following family tree will show the number of children in each generation and the degree in which they were affected by the disease:—



Great grandparents (died aged 62 and 63 years).
Great grandparents (no details known).
Grandmother. Sudden death aged 39 years; inquest.
=
Grandfather. Intemperate; died Feb. 14th, 1852, aged 40 years, from gangrene of lung which lasted four months.
Daughter. Died aged 33 years; peritonitis.
Daughter. Died aged 79 years; œdema of the lungs and angina pectoris.
Daughter. Died aged 81 years; bronchitis and asthma.
Daughter (not married). Born 1840; aphasia. Died Feb. 1880, aged 40 years; "aneurysm of heart," "atrophic softening of brain."
Daughter, married (her husband is still alive and healthy). Born 1840; aphasia, vitreous disease, and paralysis. Sudden death, December, 1878.
Daughter (not married). Born 1843; aphasia and vitreous disease. Died 1869 from hæmatemesis.
Son (not married). Still alive and quite healthy.
Son. Died aged 14 years.
Son. Died aged 23 years; aphasia, incontinence, and convulsions; sudden death.
Son. Died aged 23 years; aphasia; sudden death.
Son. Died aged 24 years; aphasia and incontinence; sudden death.
Daughter. Died aged 37 years; aphasia, incontinence, vitreous disease, and convulsions; sudden death.
Son. Died aged 27 years; aphasia, incontinence, dissociated anæsthesia, vitreous disease, and convulsions; sudden death.
Daughter. Neurotic; no symptoms of the disease; died suddenly from syncope.

The case here referred to is the daughter who died at the age of 37 years. She had suffered from vitreous opacities for nearly ten years and, like one of her aunts, had become quite blind before her death. In its general course the disease in her case resembled that of her mother and aunts, rather than that of her brothers, for the eye symptoms were prominent long before the more marked clinical features appeared and she lived to a very much greater age than any of her brothers, dying at the age of 37 years, while they died at 23, 23, 24, and 27 years of age respectively. This suggests a tendency on the part of the disease to take a different course in the two sexes, being more chronic in women, with at first much predominance of the vitreous disease, and acuter in men with early spinal symptoms. Ultimately this patient appears to have exhibited the complete syndrome of symptoms with the exception, perhaps, of the dissociated anæsthesia for she had frequent attacks of aphasia with loss of power in the right arm, convulsions of great violence and long duration, incontinence of urine (and finally also of fæces), and coma for some hours before death. It is unfortunate that no post-mortem examination could be obtained in her case to corroborate the pathological changes found and reported in the case of her brother.

Denmark-hill, S.E.

UNIVERSITY OF OXFORD: BOARD OF FACULTY OF MEDICINE.—The following have been elected members of the Board of Faculty of Medicine and will hold office until February, 1907: Sir William Selby Church, Bart., D.M., Christ Church, Honorary Fellow of University College; Walter Ramsden, D.M., Fellow of Pembroke College; Ernest William Ainley Walker, D.M., Fellow of University College; Walter William Fisher, M.A., Corpus Christi College; Samuel Hatch West, D.M., Christ Church; and William Bruce Clarke, B.M., Pembroke College.

A Mirror
OF
HOSPITAL PRACTICE,
BRITISH AND FOREIGN.

> Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv., Proœmium.

BOLINGBROKE HOSPITAL, WANDSWORTH COMMON, S.W.

SOME CASES OF ABDOMINAL INJURIES IN CHILDREN.

(Under the care of Mr. HAROLD BURROWS.)

CASE 1. *Ruptured intestine.*—A boy, aged nine years, was admitted to Bolingbroke Hospital on August 22nd, 1903. 24 hours previously, while playing in the street, he had been knocked down by a brougham, both wheels of which, it was said, had passed over his body. The occupant of the carriage at once got out and inquired how much the boy was hurt, but he declared that he was not hurt at all and subsequently he walked home, a distance of a quarter of a mile. A medical practitioner who was requested to visit and to examine the patient was unable to find any evidence of a serious injury and assured the parents that there was no harm done beyond a few bruises. However, shortly afterwards the patient began to have pain in the abdomen which soon became severe; vomiting then commenced and was repeated at intervals throughout the night and the next day, and the abdominal pain became intense. On his admission to the hospital the patient was in great pain and was frequently retching and vomiting. He said that the shaft of the carriage struck his forehead—where there was a bruise—and that both wheels had gone over his stomach. His pulse was of small volume with a frequency of 128. The abdomen was moderately distended and rigidity and tenderness were marked. There was a bruise extending from the right hypochondrium to the left inguinal region. Light percussion over the region of the liver produced a tympanitic note. Perforated bowel was diagnosed and immediate operation was performed. A median incision was made above the umbilicus and gas escaped from the peritoneal cavity. There was diffuse peritonitis. About 12 inches from the duodeno-jejunal flexure the jejunum was found to be divided completely except for a strip of mucous membrane which remained untorn near the mesenteric attachment. Much bile-stained material had escaped into the peritoneal cavity from the bowel. The gut was united, the peritoneum was cleansed by sponging, and the abdominal wound was sutured. The patient did not rally and died 12 hours after the operation.

CASE 2. *Lacerated mesentery.*—A boy, aged five years, was admitted to Bolingbroke Hospital on June 9th, 1904, having been run over a few minutes before by a hearse which was carrying to the cemetery the body of a man who had died in the hospital. Mr. E. M. W. Hearn, the resident medical officer, at once diagnosed internal hæmorrhage. On the arrival of Mr. Burrows the patient was pale and collapsed with a pulse of 160. There was dulness in both flanks. A diagnosis of rupture of the liver or spleen was made and operation was undertaken at once. A median incision above the umbilicus revealed blood in the peritoneal cavity, but the blood was mostly below the transverse colon, and an examination of the liver and spleen proved them to be undamaged. The incision was continued downwards and the mesentery was found to be lacerated in no fewer than eight places, several of the rents passing completely through the mesentery, while the largest one extended from the intestine obliquely upwards into the mesenteric root. A large vessel was bleeding at the upper end of this rent. This vessel was ligatured and the three largest rents were sutured with fine silk. The feeble condition of the child made it undesirable to prolong the operation by sewing up the smaller tears in the mesentery. The small intestine was nearly empty and was uninjured. The abdominal wound was then sutured. Although it was feared that the bowel might suffer from injury to its blood-supply no complication of this nature occurred Recovery was uninterrupted and the patient was discharged on July 1st

CASE 3 *Ruptured spleen* —A girl, aged four years, was taken to the Bolingbroke Hospital on July 26th, 1904, with the following history She was walking hand in hand with another child at a school treat when the horse in the provision cart took fright and bolted, knocking both the children down A medical man was at once summoned and was requested to examine the patient's companion who had a bruised head but he was told that he need not trouble to examine the other as she was not hurt—indeed, she was sitting in a chair eating a piece of cake and looking quite well Later in the day she complained of pain in the abdomen and became faint and was taken to the hospital On her arrival there it was noticed that she had an anxious expression as though there were some abdominal injury She complained of pain in the stomach and when asked to show where the pain was she placed her hand on the epigastrium The abdomen moved freely on respiration, was soft, and the only physical signs discovered were slight dulness in both flanks, more marked in the left, and absence of free mobility of the left costal arch The patient was not pale The pulse was 140, the temperature was 97 6° F , and the respirations were 32 Immediate operation was not advised but the nurse in charge was requested to keep a half hourly record of the pulse rate and to make known immediately any increase of its frequency Throughout the night the pulse varied between 124 and 140 but at 6 30 A M the child appeared suddenly to get faint and the pulse was found to be 168 having been 140 half an hour before On the arrival of Mr Burrows soon afterwards he found the child collapsed There were rigidity and tenderness in the left hypochondrium. The pulse was 176 and the respirations were 32 The abdomen was opened in the mid line above the umbilicus and blood was at once apparent in the recess between the stomach and the transverse colon The liver was examined and found to be intact The spleen, however, was felt to be lacerated The incision was extended to a short distance below the umbilicus The spleen could now be brought to view and was seen to be torn in halves by a horizontal rent extending beyond the hilum There seemed to be no bleeding from the lacerated spleen, but the patient was very faint no pulse being manifest at the wrist, and the pedicle had to be drawn upon in order to bring the spleen into view, either of which circumstances might have accounted for a temporary arrest of hæmorrhage The laceration was too extensive to permit of security from renewed bleeding together with conservation of the spleen, so this was removed Three interlocking silk ligatures were passed beneath the spleen and tied and the spleen was cut away with scissors a portion of its substance in the neighbourhood of the hilum being left in order to prevent the ligatures from slipping off Blood was sponged out of the abdomen and the wound was closed For 48 hours after the operation the child was in a condition of collapse with rapid feeble pulse and shallow respiration She then began to rally and for the next nine or ten days was in a curious condition She was dull, drowsy, and apathetic, but if thoroughly roused became irritable and frightened The pulse remained rapid On the evening of the ninth day after operation the temperature abruptly rose to 103 2° and the pulse increased in frequency from 92 to 168 beats a minute The wound was healthy and no physical [illegible] hich might account for the fever [illegible] ith the view that the symptoms [illegible] spleen, spleen extract and fresh bone marrow were ordered and one minim of liquor arsenicalis was also given three times a day [illegible] declined, reaching normal on [illegible] general condition appeared to improve con[illegible] A week later [illegible] to get [illegible] every [illegible] On August 24th the spleen extract was discontinued On the following day the patient was listless, disinclined to play, and usually if spoken to would begin to cry. Next day there was more marked indisposition and the child was kept in bed and in the evening the spleen extract was resumed On the following morning the temperature was 102 6° and the pulse was 150 In the evening the temperature was 99 2° and the pulse was 140 Two days later there was an evening rise of temperature to 101 2°

Ten days after removal of the spleen enlargement of the lymphatic glands of the neck, axilla, and groins was noticed The child was discharged on Sept 1st, five and a half weeks after admission She is now said to be in good health

Remarks by Mr BURROWS —Abdominal injuries are always interesting and for this reason and also because they permit of some useful comment I wish to place the above cases on record It is remarkable that in two of the cases—the torn intestine and the ruptured spleen—there were no symptoms to cause a suspicion of the grave injuries received until a considerable time had elapsed after the accident, and although similar cases have been reported before there can [illegible] heir possibility by recording two [illegible] it is important to be cautious [illegible] an opinion on a supposed case of abdominal injury To give comfortable assurances to the relatives before a few hours have elapsed is to run the hazard of a loss of reputation which will very likely be accentuated at a subsequent inquest While it is true that a grave abdominal lesion may be present without immediately giving rise to unmistakeable signs of its presence, it is equally true that well marked "peritonism" is not always an indication of severe abdominal injury About the time when Case 1 was admitted to the Bolingbroke Hospital a little girl was also taken to the children's ward, having been run over in the street a few minutes previously Her case forms a marked contrast with Cases 1 and 3 On admission she was pale and collapsed The skin was cold and sweating, no pulse could be felt at the wrist the respirations were very shallow, and it seemed as though the child were dying That there had been some violence applied to the abdomen was manifest, for the right rectus muscle was partially [illegible] Nothing was done beyond th[illegible] and other stimulants A little [illegible] somewhat and the pulse, though very rapid, could be distinguished at the wrist There now appeared great pain and tenderness in the upper part of the abdomen but the liver dulness was unimpaired and there was no dulness in the flanks The pulse showed a rapid and continuous improvement and the respirations became deeper On the following day the child appeared quite recovered except for tenderness in the place where the rectus muscle was injured No further symptoms developed and the patient was discharged a few days after her admission

Perhaps the different degrees of sensitiveness of the visceral and parietal peritoneum are sufficient to account for the unreliability of pain as a symptom in abdominal injuries It has been shown that the visceral peritoneum is nearly insensitive and therefore injury to the gut or spleen without injury to the parietal peritoneum does not cause pain until peritonitis due to hæmorrhage or sepsis has ensued The child mentioned above as a contrast case may have suffered from a tear of the parietal peritoneum without severe visceral injury The conclusion to be drawn from these and other similar cases is that symptoms of peritonism do not justify an exploratory operation in cases of abdominal injury unless they persist or else are associated with definite physical signs such as loss of liver dulness, dulness in the flanks, or an increasing frequency of the pulse

Loss of liver dulness —There appears to be much difference of opinion among surgeons as to the value of this sign The confusion is probably due to the different methods of percussion employed Among 50 consecutive abdominal emergency cases which have recently been under my care loss of liver dulness on gentle percussion was observed in six only, and in every one of these six a perforation of gut other than the appendix was found at the operation or the necropsy The six cases were as follows two perforated gastric ulcers, one perforated stomach due to swallowing hydrochloric acid, one perforated duodenal ulcer, one traumatic perforation of the rectum (without a history or external evidence of any such injury), and the case of ruptured intestine referred to above In no case where liver dulness was present was there a perforated gut (other than the appendix) In only three other emergency cases has there been absence of liver dulness, in one due to a stab wound of the left lung and diaphragm without intestinal injury and in the other two to pneumothorax One of these is worthy of a brief mention A boy, four years old, was run over by a cart [illegible] over his epigast[illegible] discovered that [illegible] rupture of the intestine. However, the true nature of the case soon became apparent. There were no broken ribs and two days later the patient was quite well, although a few hours after the injury there was considerable dyspnœa and the respirations were between 50 and 60 a minute. Such cases are not very uncommon in children where injury has been received to the lower part of the thorax.

The following propositions with regard to loss of liver dulness appear to be warranted: (1) that if light percussion over the front of the liver yields a tympanitic note there is free gas between the liver and the percussed finger; and (2) that this gas may have escaped from lung or from stomach or intestine. The highest importance may therefore be attached to loss of liver dulness as a symptom in abdominal emergencies but the percussion must be of the lightest character. Heavy percussion will yield a resonant note over the liver in the absence of free gas if there be much intestinal distension. A tympanitic note elicited by gentle percussion is conclusive proof of the presence of free gas in front of the liver.

Blood in the abdominal cavity.—A striking feature of Cases 2 and 3 was the small quantity of blood found in the abdomen. Although there was sufficient to cause dulness to percussion in the flanks there was by no means a quantity proportionate to the constitutional symptoms of hæmorrhage. It seemed probable that though much blood had been effused it had been rapidly absorbed by the peritoneum. The remarks on the necessity for gentle percussion in testing the liver dulness apply with equal force to the examination for fluid in the flanks. Small quantities will be overlooked if the percussion is forcibly performed.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

The Influence of Stigmata of Degeneration upon the Prognosis of Epilepsy.—A Group of Associated Malformations, including almost Complete Absence of the Muscles of the Abdominal Wall and Anomalies of the Genito-urinary Apparatus.

A MEETING of this society was held on Feb. 14th, Sir RICHARD DOUGLAS POWELL, Bart., the President, being in the chair.

Dr. W. ALDREN TURNER read a paper on the Influence of Stigmata of Degeneration upon the Prognosis of Epilepsy. The purpose of the communication was to ascertain, by means of a statistical investigation, whether the presence of structural stigmata of degeneration exercised any influence, and if so to what extent, upon the prognosis of epilepsy. Stigmata of degeneration were defined as structural deviations from the normal, arising during the periods of development and brain growth, in those who were the subjects of a hereditary degenerative predisposition. 100 consecutive cases of confirmed epilepsy from amongst the patients resident at the Colony for Epileptics, Chalfont St. Peter, were examined with this object. The stigmata to which attention was especially directed were: (*a*) Facial, including nasal, deformity and asymmetry. This was found to be more common in females than in males. Although present in 42 per cent. of the total number of cases it was only found in 14 per cent. as a single stigma. (*b*) Deformities of the hard palate. These form some of the most frequent and trustworthy of degenerative phenomena. Abnormal palates were found in 42 per cent. of the cases but only in 17 per cent. as a solitary stigma. (*c*) Deformities of the external ears, indicated by abnormal size, shape, and symmetry, were present in 33 per cent. but in only 9 per cent. as a solitary stigma. (*d*) Dental anomalies and displacements. Brief reference was also made to stammering and high errors of refraction as physiological stigmata. The statistical facts bearing upon prognosis were considered under the following headings:—1. Sex. Of 100 epileptics 62 were males and 38 were females. Males exhibited neuropathic stigmata to a much greater extent than females in the proportion of 52 males to 23 females. Of the total number of cases, males and females, 75 per cent. presented stigmata and 25 per cent. were free. 2. Hereditary history. Owing to the difficulty in obtaining precise and trustworthy information on this point it was not possible to deduce any general conclusions but it was observed that direct parental heredity to epilepsy or insanity was usually associated with more pronounced stigmata than collateral heredity. 3. Age at onset of the convulsions. Those cases in which the disease commenced between birth and five years of age showed a larger percentage of stigmata than at other ages. This was in harmony with what had been shown elsewhere that epilepsy commencing during the first quinquennium was characterised by the highest percentage of cases showing profound mental impairment and was most favourable for the development of the confirmed malady. 4. It was apparent from a study of the duration of the convulsions that the absence of stigmata did not necessarily imply an early or favourable termination of the disease. 5. The type of the seizures. The greatest difference in the proportion of cases with and without stigmata was observed in those which presented the combined *grand* and *petit mal* type. Such combination had also been shown to be associated with the highest grades of dementia. The purely petit mal type did not exhibit marked evidence of hereditary degenerative disposition. 6. The relation between the presence of stigmata and *the mental state* was especially obvious. Those epileptics who only showed the slighter degrees of mental impairment presented a nearly equal proportion with and without stigmata (21 per cent. with and 19 per cent. without). On the other hand, of those in whom there was marked mental enfeeblement 53 per cent. exhibited, and only 7 per cent. were free from, them. Hence there would appear to be a close association between degrees of mental impairment and the presence of neuropathic stigmata, a fact which was proffered as an argument in favour of the view that the interparoxysmal mental condition in epilepsy was an integral part of the disease.—Dr. C. H. BOND stated that although the epileptics in his charge at the Ewell colony were under the Lunacy Act his statistics on the questions under discussion bore a strong resemblance to those of Dr. Turner. He thought that additional value would be given to such statistics by mentioning the ages of the patients at which the various stigmata had been observed. An important advance would be made when congenital and acquired conditions of idiocy were separately dealt with.—Mr. STEPHEN PAGET asked whether the stigmata mentioned were related especially to epilepsy or were general in neuropathic conditions and what essential difference there was between the appearance of such malformations as had been referred to and the antenatal factors which lay behind variations in height and stature. He believed a certain amount of asymmetry to be general and the presence of badly formed palates and jaws almost universal in the London poor.—Dr. G. E. SHUTTLEWORTH thought that the presence of a single stigma was of little importance but the combination of two or three or more was certainly an evidence of degeneration. He agreed that the percentage of developmental defects was much greater in males than in females but that when they did occur in the latter they were likely to be strongly marked.—Dr. FLETCHER BEACH asked for Dr. Turner's experience of cranial abnormalities such as microcephalus, hydrocephalus, and changes in the skull as the result of paralysis. Had any cases of webbed fingers been noticed in the series of cases?

Dr. A. E. GARROD and Dr. LL WYNNE DAVIES communicated a paper on a Group of Associated Malformations, including almost Complete Absence of the Muscles of the Abdominal Wall and Anomalies of the Genito-urinary Apparatus. Dr. Garrod and Dr. Davies described in detail the clinical features and the post-mortem appearances observed in the case of a male infant which presented a malformation-complex such as had been described in a few other cases which had come under observation in this country, in America, and on the continent of Europe. These cases had been collected and discussed by Stumme of Leipsic in a very complete monograph published in 1903. The deformities in question, which were evidently inter-related, included:—(1) Almost complete absence of the muscles of the abdominal walls; (2) hypertrophy and dilatation of the urinary bladder which had in most instances been attached to the umbilicus either directly or by a urachus; (3) a linear scar-like umbilicus; and (4) undescended testicles. In several cases, as in the one here described, there had been deep furrowing of the skin of the abdomen. Owing to the absence of muscles the abdominal viscera could be felt with very remarkable distinctness. Some other deformities were present in this case, such as double talipes varus. The child died from broncho-pneumonia and erysipelas and Dr. Garrod and Dr. Davies were able to include a report by Dr. F. E. Batten on the microscopical appearances of the vestiges of muscular substance in the abdominal walls and upon the condition of the spinal cord of the patient. The spinal cord had not been examined in any previous fatal case and a gap in their knowledge was thus filled in. The possibility that the condition of the muscles was due to intra-uterine poliomyelitis was excluded by Dr. Batten's report. Brief abstracts were included of the few similar cases hitherto recorded and the resemblances between them and the differences which they presented were discussed. Dr. Garrod and Dr. Davies favoured the view which was advocated by Stumme in his monograph that of the three possible theories—viz.: (1) that the condition of the bladder is due to the non-development or atrophy of the muscles; (2) that the two malformations have a common cause; or (3) that the non-development or atrophy of the muscles is secondary to a temporary obstruction of the escape of urine occurring during intra-uterine life—the last was the most likely to be correct. No existing obstruction was found in any case, but the distension of the bladder, and in some cases of the ureters also, suggested that such had existed at some period. As all the cases hitherto observed had been in males it was tempting to ascribe the supposed obstruction to a kinking or constriction of the penis, but it might be that, as Stumme suggested, the attachment of the bladder to the umbilicus was the primary cause. However, such attachment had not been invariably present, even in cases in which the navel had the characteristic slit-like form. Dr. Batten considered that the microscopical appearance of the vestiges of muscles in the abdominal walls pointed to non-development and not to atrophy of originally developed muscles. Stumme ascribed the non-descent of the testicles to occlusion of the inguinal canals by intra-abdominal pressure.—The PRESIDENT emphasised the importance of the paper and of putting on record every case of the kind, as they evidently belonged to a well-defined symptom-complex.—Dr. L. G. GUTHRIE preferred to believe that the condition owed its origin to a primary non-development of the abdominal muscles and explained how such a condition would give rise to hypertrophy of the bladder wall and other anomalies. He believed that the attachment of the urachus to the anterior abdominal wall might give rise mechanically to obstruction of the ureters and thus to their overgrowth. There was no direct evidence of any temporary obstruction to the escape of urine during intra-uterine life and such a condition would have to operate a very long time to bring about the muscular atrophy found in these cases, even if that was the natural result.—Dr. E. FARQUHAR BUZZARD was incline to agree with Dr. Guthrie and supported the view that arrested development of the abdominal muscles might be held to explain the other abnormalities in these cases. Before hypertrophy of the bladder had time to arise dilatation of the bladder and ureters would take place owing to the accumulation of secretion which was not properly expelled in the absence of abdominal muscular contraction. He cited other instances of congenital symmetrical absence of certain muscles which he had observed.—Dr. G. NEWTON PITT asked whether the anterior or the posterior bladder wall was the more hypertrophied. In ordinary cases of chronic vesical enlargement the anterior wall was much thicker than the posterior; in the absence of the abdominal muscles he would expect the thickening to be general.—Dr. GARROD replied.

MEDICAL SOCIETY OF LONDON.

Exhibition of Cases.

A MEETING of this society was held on Feb. 13th, Mr. JOHN LANGTON, the President, being in the chair.

Dr. T. R. GLYNN showed a case simulating Intracranial Tumour in which there was spontaneous and persistent escape of cerebro-spinal fluid from the nose, with complete recovery. A man, aged 26 years, in August, 1898, received a blow on the vertex of the head which caused temporary loss of consciousness, headache, and vomiting, and compelled him to give up work. In a month's time the pain was paroxysmal and was associated with vomiting and dilatation of the pupils. Double vision was complained of within two months of the accident. His memory failed and he suffered from vertigo and choking sensations. On examination there was weakness of the left external rectus; the knee-jerks were exaggerated and the plantar reflexes were absent; the abdominal and cremasteric reflexes were less marked on the left than on the right side. Certain hysterical stigmata, left hemianalgesia, and concentric restriction of visual fields were also observed. Early in 1899 optic neuritis developed and he complained of giddiness when he stooped, with a tendency to fall forward. After some temporary improvement he gradually became worse and the deterioration continued until June, 1903, with progressive failure of intellect and of muscular power. His gait became reeling with some propulsion on going downhill. His arms were ataxic and presented volitional tremors. His sight almost completely failed and nystagmus was noted. The superficial reflexes were absent and ankle clonus was present. During 1903 he had several epileptic attacks and suffered from incontinence of urine. In June, 1903, clear fluid commenced to flow from the right nostril and very soon improvement set in, followed by complete recovery in the course of a few weeks.—Dr. E. E. GLYNN explained with the aid of a diagram how the symptoms may have been due to internal hydrocephalus and may have been relieved by spontaneous drainage of the fluid from the distended lateral or third ventricle along the perineural sheaths of the olfactory nerves and so into the nasal cavity.—Dr. STCLAIR THOMSON said that the case supported his theory that spontaneous rhinorrhœa of cerebro-spinal fluid was always the result of internal hydrocephalus. He believed that the fluid escaped directly into the roof of the nose and not into the accessory cavities. Many patients with cerebro-spinal rhinorrhœa died from meningitis.

Mr. W. BRUCE CLARKE showed a case of Cancer of the Stomach one year after pylorectomy. A man, aged 59 years, was admitted into St. Bartholomew's Hospital on Jan. 9th, 1904, suffering from symptoms of cancer of the stomach. The abdomen was opened a fortnight later and the stomach, which was much thickened at the pyloric end, was found to be adherent to surrounding parts. No glands could be felt. The stomach was cut across about two and a half or three inches from the pylorus and about one inch of the duodenum was removed at the same time. Openings in the stomach and duodenum were reduced to the same size and united end to end. The patient made an uneventful recovery and was able to go to a convalescent home about a month later. An examination of the growth showed that the bulk of it was non-malignant in character and was due to the thickening which had occurred around an old ulcer. Close to the pylorus was a small patch of malignant ulceration showing columnar-celled characters. He thought that the case afforded direct evidence of a benign growth in the stomach becoming malignant. There was no sign of any recurrence of the disease.—Dr. E. SYMES-THOMPSON cited another case where the character of the lesion suggested a primary innocent with a secondary malignant condition.—Dr. A. F. [illegible] whether the patient had been tested for free [illegible] before operation.—Dr. F. J. [illegible] impossible to tell clinically [illegible] of the stomach was innocent or malignant and he agreed that ulceration in the region of the pylorus produced symptoms out of proportion to its extent, whereas large diseased areas nearer the cardiac orifice were often unsuspected before a necropsy revealed their presence.

Mr BRUCE CLARKE also showed a case of Oöphorectomy for Cancer of the Breast five years after operation. In 1890 a woman, aged 46 years, noticed a small lump in her breast and five years later blood-stained discharge from the nipple. In April, 1897, there were two lumps in the breast and Halstead's operation was performed. Two or three more operations were performed for glands above the clavicle but abundant recurrence took place accompanied by much pain in the neck and the arm. In March, 1900, double oöphorectomy was performed. Within 48 hours the pain ceased and before [illegible] the skin growth had begun [illegible] months, when she reached [illegible] exception of occasional attacks of pain she had remained well and was able to do all her ordinary household work.

Mr. H. J. WARING showed a case of Double Oöphorectomy for Carcinoma of the Breast. A single woman, aged 37 years, came under observation in September, 1904, when she was found to have a large carcinomatous growth of the right breast which had first been noticed about two years previously. Ulceration of the skin had begun about two weeks before coming under observation. The growth involved the whole mammary gland as well as the underlying muscles and was firmly fixed to the chest wall. Enlarged axillary glands were also present. Double oöphorectomy was performed on Sept. 27th and the patient made a rapid recovery. When discharged a month later the tumour had diminished in size and the general condition of the patient had improved. Since then little change had taken place, although the lymphatic glands in the axilla seemed to be a little smaller.—Mr. A. **CARLESS** stated that he had performed oöphorectomy in 12 cases of mammary scirrhus and had always found that pain was relieved, that the growth and the glands diminished in size, and that the patients were often able to go about their ordinary work for two or three years in comparative comfort. He advocated complete removal of all growth at the same time as oöphorectomy.

Dr. **POYNTON** showed two cases of Exophthalmic Goitre. 1. The patient was a man, aged 23 years, who had noticed for four months that his right eye was more prominent than his left. He was very nervous and suffered from palpitation and sweating after exertion. The thyroid was slightly enlarged and there was some fine tremor of the hands. The heart was not rapid at rest but was easily excited. No local cause for the proptosis could be discovered. 2. The patient was a boy, aged nine and a half years, who had recently become exceptionally nervous and had been taken to the Hospital for Sick Children on account of swelling of the thyroid. Persistent tachycardia was noticed with the occasional presence of von Graefe's sign. There was some coarse but no fine tremor of the hands.—Mr. A. **THORNE** asked whether there was any explanation of the unilateral character of the proptosis.

Dr. J. **BRUNTON** exhibited a case of Aneurysm of the Descending Arch of the Aorta appearing externally to the Left of the Spinal Column. A man, aged 43 years, had complained of pain over the left side of the thorax for 12 months. Early in December, 1904, a swelling was noticed between the vertebral border of the left scapula and the spinal column and this had increased in size. On auscultation a soft bruit could be heard over the pulsating area during both expansion and recoil. There was no abnormal pulsation in front, the second aortic sound was accentuated, and both the respiratory murmur and movements were diminished on the left side of the chest. There was no dysphagia, laryngeal symptom, or inequality of pupils. Arterial degeneration was not marked. A skiagram had not given substantial help to the diagnosis. —Dr. H. E. **BRUCE PORTER** inquired whether it was possible for an aneurysm to bulge so much without giving rise to pressure symptoms.—Dr. C. O. **HAWTHORNE** did not think that the case was one of aneurysm as he had never seen one where the ribs were so eroded in the absence of other evidence of pressure.

Dr. W. **EWART** showed two cases of Diabetes. 1. A man, aged 26 years, was admitted into St. George's Hospital with a history of a few weeks' rapid loss of flesh and strength with polydipsia and with symptoms of threatening coma and strong acetonæmic smell. The urgent symptoms were quickly relieved by large doses of sodium bicarbonate (up to six drachms three times a day) and by dieting. The urine remained acid until Feb. 5th when the dose of sodium bicarbonate was reduced to four drachms, the acid reaction then returning. At present he was having five drachms of sodium bicarbonate, 30 grains of hypophosphites, and 20 minims of liquor strychninæ three times daily. His diet restrictions were not absolute and his progress was satisfactory, there being only a faint smell of acetone in the breath. He passed about three and a half pints of urine daily of specific gravity 1030. 2. A man, aged 24 years, was admitted for polydipsia and weakness of three weeks' standing. The condition was possibly due to excessive consumption of jams, marmalade, and starchy food. His weight was 9 stones 7 pounds; he was passing about five pints of urine daily of specific gravity 1040, and the percentage of sugar was 8·5. He improved rapidly under restricted diet, the sugar disappearing altogether for six days. With the exception of the sodium bicarbonate he had had the same treatment as the first patient and his present weight was 10 stones 4 ounces. He was passing three and a quarter pints of urine daily of specific gravity 1030.

Dr. W. **ESSEX WYNTER** showed a case of Tumour of the Left Lobe of the Cerebellum. The patient, aged 36 years, was laid up with vomiting and constipation in July, 1904. He recovered from this but in August noticed that he became easily fatigued and was told that he walked as if intoxicated. Left facial palsy and deafness in the left ear came on about this time. In September the right leg became too weak and unsteady to bear his weight but he was able to walk with a stick when first seen in January, 1905. Now the gait was partly spastic and partly ataxic; there was complete left facial palsy and complete nerve deafness of the left side. He complained of some vertigo and occipital headache and presented nystagmus and dilatation of the left pupil. The deep reflexes were brisk and there was double extensor response. The optic discs were pink, with vessels full, but there was no definite neuritis.

CLINICAL SOCIETY OF LONDON.

A Case of "Soft-valve" Mitral Stenosis without Murmur.—A Case of Accessory Thyroid laterally placed in the Floor of the Mouth.—Extraperitoneal Uretero-lithotomy in a Child, aged three years.—Calculous Anuria in a Child, aged four years.

A MEETING of this society was held on Feb. 10th, Dr. **FREDERICK TAYLOR**, the President, being in the chair.

Dr. W. **EWART** recorded a case of "Soft-valve" Mitral Stenosis in which no murmur was heard. The patient, a woman, aged 45 years, was under observation for two months before death and during that time no suspicion of the existence of mitral stenosis was aroused and no diastolic murmur was heard. At the necropsy considerable narrowing of the mitral orifice was present but the valve, the chordæ tendineæ, and the musculi papillares showed very little induration. The heart was enlarged, the muscle was flabby, and the other valves were competent. The clinical value of the case lay in the undoubted character of the lesion and in the independent testimony of various observers, during a long period of hospital treatment, as to the absence of murmurs, demonstrating the fact that the characteristic bruits may sometimes be in abeyance for prolonged periods at an advanced stage, though more often in abeyance for short intervals only at an early stage. The anatomical features of the lesion; of special interest in connexion with this latency, were fairly described by the term "soft-valve stenosis," which might be of use in defining a separate type of lesion in which the early fibrous changes did not, as in the "hard-valve stenosis," develop into progressive thickenings and indurations. The action of a relatively soft stenosed mitral valve must be different from that of the rigid stenosis, particularly when, as in this instance, the chordæ tendineæ and the papillary muscles were quite free from stiffness, shortening, or fibrosis. The absence of murmur where this complication was also absent might perhaps, if observed in other cases, be an argument in support of the prevalent view as to the auriculo-systolic mode of production of the presystolic mitral murmur and as to the share taken by damaged chordæ in occasioning diastolic murmurs.—Dr. **SEYMOUR TAYLOR** said that he regarded the absence of the proper auricular driving force as the essential factor in the disappearance of a presystolic mitral murmur and suggested that it was the cause in Dr. Ewart's case. He did not think that the softness of the valve alone would explain the absence of bruit. With regard to the causation of mitral stenosis he was of opinion that in the majority of cases the valvulitis was the result of rheumatism or chorea before puberty, in consequence of which the diseased valve did not keep pace with the development of the rest of the organ. After puberty mitral endocarditis more commonly gave rise to incompetence and rarely to stenosis.—Dr. F. **PARKES WEBER** mentioned a case of mitral stenosis with the ring partially calcified, in which the presystolic murmur had disappeared during cardiac failure.—Dr. W. **PASTEUR** asked whether Dr. Ewart had noticed any alteration in rhythm or in the character of the first sound suggestive of narrowing of the mitral orifice.—Dr. W. **ESSEX WYNTER** thought that the thinness and the yielding character of the valve were of particular interest and might have contributed to the absence of murmur. In his experience mitral stenosis was not found in children under seven and rarely in children between seven and 14 years of age. He agreed with Dr. Seymour Taylor that the continuance of the infantile type of valve owing to disease in early life was often the cause of mitral stenosis. The history of rheumatism was often difficult to obtain on account of the slight character of the symptoms and the absence of arthritis in children.—Dr. F. H. HAWKINS mentioned the case of a woman, 56 years of age, who was under observation for a month before death and had no cardiac murmur. Post mortem there were mitral stenosis and thrombosis of the abdominal aorta and its branches.—The PRESIDENT agreed with Dr. Seymour Taylor that the character of the valve was not sufficient to explain the absence of bruits and pointed out that the left auricle was free from evidence of hypertrophy.

Mr. E. PERCY PATON recorded a case of Accessory Thyroid in the Floor of the Mouth. A girl, aged 16 years, noticed a swelling on the right side of her neck in the submaxillary region for some months before coming under observation. It gave her no pain but she w [illegible] size. It was situated in [illegible] could be felt from inside [illegible] The diagnosis before operation was uncertain but on microscopical examination after removal it was shown to consist of thyroid tissue. In studying the literature of accessory thyroids he had been unable to trace any similar case.—Mr. W. G. SPENCER showed an illustration from a paper by Wilhelm His on the Development of the Thyro-glossal Duct which, he thought, explained the presence of thyroid tissue in the situation where it was found by Mr. Paton.

Mr. H. BETHAM ROBINSON described a case of Extraperitoneal Uretero-lithotomy in a child, aged three years. The child upon whom this operation was performed was admitted to the East London Hospital for Children on June 17th, 1904, with an impacted calculus in the urethra. On examination, after this stone had been extracted, there was felt bimanually a small hard lump on the left side of the pelvis just below its brim which was diagnosed as an impacted calculus in the ureter; the corresponding kidney did not appear to be enlarged. After waiting a few days for the urethral wound to heal and to see whether the stone was making its way to the bladder, which it did not do, he performed uretero-lithotomy and removed a small oval calculus. A fine catgut stitch was put through the outer part of the ureter and a wick drain was left in the wound down to it. The rest of the wound was sewn up with horsehair. There was very slight leaking for three days; after that the wound healed rapidly. There was no blood in the urine after the operation. From an experience of three cases, two in the adult and this child, he considered the operation easier in the child for the following reasons: the small quantity of fat in the [illegible] connective tissue and [illegible] position of the bladder. [illegible] rectum to push the ureter with the impacted stone well up into the wound.

Mr. DOUGLAS DREW read the notes of a case of Calculous Anuria in a child. A boy, aged four years, was admitted into hospital with stone in the bladder and cystitis for which suprapubic cystotomy was performed and the bladder was drained. After the operation the child did not make good progress. The pus persisted in the urine, there were occasional rises of temperature [illegible] did not completely heal. [illegible] of pain in the abdomen bu [illegible] repeated examinations except slight tenderness over the left kidney. This symptom, together with the persistence of the pyuria and irregular attacks of temperature, led to the diagnosis of septic trouble in the left kidney. At the end of four months the child was seized with severe pain and a stone was found impacted in the meatus and was removed. After this marked improvement occurred, the sinus above the pubes closed, the temperature kept normal, and the condition of the urine greatly improved. A month later the child began to vomit, pain recurred in the abdomen, the urine again became alkaline and contained pus and blood, and the wound above the pubes again began to leak. At the same time the quantity of urine, which had been measured daily, diminished from 25 ounces to between seven and 19 ounces. Two radiographs taken at intervals of a few days about this date gave negative results. A few days later the abdominal pain became more severe and for the first time was referred to the left inguinal region. Examination under chloroform showed that the left kidney was enlarged and that the right was of normal size. Per rectum a stone of triangular shape was felt in the left ureter just below the brim of the pelvis. The left kidney was at once exposed and a calculus was found and removed from it; the wound was extended forwards and the calculus in the ureter was manipulated up along it and removed through an incision just below the pelvis. The right ureter could be distinctly felt through the wound and was enlarged; this was the first positive sign of trouble on the right side, as the stone which was found post mortem in the lower end of the right ureter had been missed on palpation per rectum, and there had been no symptoms referred to the right side. The child's condition did not permit of exploring the right kidney at the time the stones were removed from the left side, and although he lived six days after the operation the condition did not improve sufficiently for any further interference. The vomiting persisted, drowsiness increased, and the quantity of urine per urethram gradually diminished, only two and a half ounces being passed during the last three days. The chief point of interest was the difficulty in diagnosis, owing to the negative results of radiography and the very slight degree of pain occasioned by the stones. The case was extraordinary in that calculi were removed from the bladder, the urethra, and the left ureter and kidney.—Mr. PATON referred to a death from unsuspected calculous anuria in a child who had been operated on for cleft palate. There had been no urinary symptoms previous to the operation.

OPHTHALMOLOGICAL SOCIETY.

Tobacco Amblyopia.—Neuro-fibroma of the Eyeball and its Appendages.—Exostosis of the Orbit.

AN ordinary meeting of this society was held on Feb. 9th, Mr. JOHN TWEEDY, the President, being in the chair.

Mr. C. WRAY (Croydon) read a paper on Tobacco Amblyopia. He divided cases of tobacco poisoning as seen in ophthalmic practice into three categories: (1) those with toxic amblyopia; (2) those with amblyopia and tachycardia; and (3) those with tachycardia alone. He contended that in view of the tendency to cardiac failure in various febrile conditions ophthalmic surgeons as a matter of routine should examine the pulse. During the last eight weeks several cases of toxic amblyopia had come under his notice at the Western Ophthalmic Hospital and the Croydon General Hospital, in which the pulse was 96, 84, 135, and 96 to 120. Such cases proved that patients with defective sight due to tobacco should be warned that tachycardia might come on without any such peremptory warning as defective sight. He then asked. Does giving up tobacco entirely cure amblyopia and tachycardia? and stated that the amblyopia usually disappeared if taken early but in all cases the convalescence under recognised treatment was very protracted and occupied many weeks. As regarded the tachycardia it was not easy to make a positive statement but in several cases which he quoted the tachycardia had not disappeared after tobacco had been given up for several years. He alluded to toxic breath and stated that although it was probably always present with toxic amblyopia it was never present when tachycardia existed as the sole manifestation of the poison and he was inclined to think that tachycardia was due to injury or destruction of the cardio-inhibitory neurons in the trachea and bronchi. The amblyopia, he believed, was due to saturation of the blood with tobacco alkaloids and he would explain the relative frequency of amblyopia as a toxic manifestation by the accuracy with which we could gauge the physiological condition of the papillo-macular neurons. He suggested as an explanation of poisoning in some cases and not in others that this was not so much due to idiosyncrasy as to the accident of bad teeth so common in heavy pipe-smokers and so fatal in phosphorus workers, possibly also, and indeed probably, to the condition of the mucous membranes of the alimentary and respiratory tract, in harmony with the rule that when the epithelium was absent or defective substances were more readily absorbed as the poisons were brought into intimate contact with the capillaries. Mr. Wray then went on to say that for some time he had abandoned the orthodox treatment by strychnine and potassium iodide as the results were uniformly unsatisfactory. He then pointed out that nicotine was used to paralyse "ganglion cells" and it was precisely the ganglion cells that suffered in the retina. In the circumstances it seemed justifiable to infer that nicotine was the hypothetical cause of amblyopia and, since that alkaloid was freely soluble in water, that not improbably water might be made to aid in the elimination of the poison. With that object in view his patients were directed to dress warmly and to drink one pint of warm water at 7 A.M. and to walk briskly for 30 minutes in the open air; then to drink a second pint and to walk briskly in the open air for another 30 minutes, after which to rest for a few minutes and then to take breakfast. A third pint should be taken in the middle of the morning and a fourth in the middle of the afternoon. Some of the patients during convalescence smoked a quarter of an ounce of tobacco a day and in three cases practically normal vision was secured in about 14 days, whilst according to some of his notes patients under the strychnine treatment were as long as 12 weeks in obtaining an equally good result. As regarded the effect of the water treatment on tachycardia, he had not had an opportunity of trying it as the new cases of amblyopia that had come under his treatment during the last eight weeks had only a very slight acceleration of the pulse-rate but unquestionably it had not disappeared in the same way as the amblyopia. He thought that there was considerable doubt as to the method of elimination of nicotine. It was excreted by the kidneys, the lungs, and the skin; he thought mostly by the kidneys, *others by the breath, and others by the skin*, but the water treatment had this advantage, that it utilised all three methods.

Mr. E. TREACHER COLLINS and Dr. RAYNER D. BATTEN communicated a paper on Neuro-fibroma of the Eyeball and its Appendages. The case which formed the basis of this paper was that of a girl, aged 14 years, who had been under Dr. Batten's observation since January, 1902. Her right eye was buphthalmic. The cornea was large and hazy and the anterior chamber was very deep. The vision equalled $\frac{1}{60}$. There was also marked hypertrophy of the upper eyelid, the skin of which was coarse and thickened, and there was a soft doughy swelling over the right temporal fossa. The condition dated from birth. The eye being very unsightly and irritable was excised, as was also a wedge-shaped piece of the thickened upper lid. Microscopical examination of the latter showed extensive overgrowth of the fibrous tissue of the corium and marked enlargement of the nerves due to thickening of their peri- and endo-neurium. The condition was evidently one of congenital elephantiasis associated with plexiform neuroma, a condition to which the convenient term neuro-fibromatosis was applied. The chief interest of the case consisted in the condition of the eye. This made the fourth case which had been recorded in which neuro-fibromatosis of the eyelid had been associated with a buphthalmic condition of the eye. The buphthalmic condition of the eye did not, however, seem to be due directly to fibromatosis of the ciliary nerves but to increased tension from obstruction to the exit of fluid. In the present case and another one which Mr. Collins had examined he found congenital adhesion of the root of the iris to the back of the cornea blocking the filtration area. The terminal filaments of the nerves in the cornea were, however, found thickened; they could be seen by the naked eye as grey lines and microscopically as cords of elongated cells. The condition of the choroid in this case was most remarkable and presented appearances which did not seem to have been described previously. Throughout its structure was denser than normal and in parts it was considerably thickened. Microscopically the blood-vessels in it were few and inconspicuous. It was composed of fibrous tissue arranged in layers, highly nucleated, and with many pigmented cells between them. In some places there were numerous small oval bodies which presented the appearance of enlarged nerve-end organs. In conclusion, by a comparison of this case with the few others recorded it was shown that all portions of the ciliary nerves supplying the eye might be affected by this congenital fibromatosis and that in the uveal tract, as in the skin, associated with the neuro-fibromatosis there might be a general hyperplasia of the fibrous tissue of the part. The extent, however, of the affection varied in its distribution, sometimes being confined to one set of ciliary nerves and the part supplied by them and sometimes to another. In some cases only the terminal filaments and end organs of the nerves were involved and in others the larger trunks were also affected.

Mr. A. OGILVY (Bristol) reported a case of Large Exostosis removed from the Orbit. The patient was a healthy man, aged 24 years. There was no previous history of any ailments and there was a healthy family history. The patient was first seen last November; he did not know there was anything in his orbit—he merely came because of epiphora. A large hard mass was felt in the right orbit, evidently growing from the nasal side. Skiagraphs were made showing well the extent of the tumour which was evidently causing myopia and some form of choroidal change. The operation was performed on Jan. 1st, 1905. Great difficulty was experienced in removing the tumour which, however, proved to be pedunculated and measured over an inch in each direction. Recovery after operation was rapid, union being by first intention. The only trouble was diplopia, caused by complete immobility of all the muscles; this passed off in a fortnight.

Mr. EDGAR STEVENSON also described a case of Exostosis of the Orbit. The patient, a girl, aged 22 years, went to the Liverpool Eye and Ear Infirmary on Nov. 20th last with well-marked downward and outward proptosis of the left eye. She stated that the prominence of the eye had been first noticed six months previously and that it was rather rapidly increasing. She had no pain except an occasional neuralgic twinge, the movements of the eye were quite free, and she was not troubled with diplopia. Her vision in each eye was normal with correcting glasses, as also was the fundus of each eye. Digital examination under chloroform revealed a small hard mass lying under the outer and upper margin of the orbit. Three weeks later Mr. Stevenson decided to operate and on Dec. 10th the patient was again put under chloroform and the tumour was exposed. It was found that the growth was much larger than was to be expected from the previous examination. It seemed to be attached to the inner angle of the orbit with its base in the frontal sinus and to extend right across the roof of the orbit. Two attempts to drill through the more prominent part failed on account of the drills breaking and Mr. Stevenson then attempted to chisel through the frontal sinus in order to expose the base. A small part of the tumour here became detached and showed cancellous structure underneath a hard outer shell. There appeared to be some "shake" in the tumour during the chiselling which seemed to indicate that the point of attachment was not very large, so having ascertained that there was not any apparent involvement of the roof of the orbit the tumour was seized with a pair of bone forceps and wrenched out without difficulty. It was of irregular pear shape, weighed 351 grains, and its dimensions were one and a half inches by one and three-eighths inches by seven-eighths of an inch. The patient made an uninterrupted recovery and her vision, muscular balance, and ophthalmoscopic appearances are normal.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

Paratyphoid Fever.—Large White Kidney.

A MEETING of this section was held on Jan. 20th, Sir J. W. MOORE being in the chair.

Dr. A. R. PARSONS read notes on three cases of continued fever in which for some time the diagnosis was obscure. They all occurred in the same building and at about the same time. The first proved to be a severe case of typhoid fever and gave a definite Widal reaction with Eberth's bacillus typhosus on the twelfth day of the illness. The pyrexia lasted for 50 days. The second case, though tested on three separate occasions by different strains of bacillus typhosus, gave no reaction but gave very definite clumping with Gärtner's bacillus *enteritidis* on two occasions and with different strains. The pyrexia lasted for 21 days. Case 3 was also negative with bacillus typhosus but positive with Gärtner's bacillus. The pyrexia lasted for 14 days. In all the cases the subjective phenomena were headache and malaise. The objective signs were temperatures of from 102° to 104° F., while the average pulse rate was only 90. In none of the cases was the spleen palpable and only in the first case were any spots visible. Cultures were made from the urine and fæces in the latter cases but the bacillus enteritidis was not isolated. Dr. Parsons referred to cases of paratyphoid fever reported in the *American Journal of the Medical Sciences* and pointed out the necessity for isolating various strains of the *bacilli* of paratyphoid fever against which the blood of obscure cases

of continued pyrexia might be tested Owing to the general absence of ulceration in paratyphoid fever he was of opinion that the diet need not be quite so strictly regulated as in typhoid fever —Dr J CRAIG described minutely the fatal case of paratyphoid fever which he had seen The patient was a man whose appearance suggested typhoid fever His temperature was 103 2° F and his pulse and respirations were 100 and 24 per minute respectively He had three liquid yellow motions and developed a rash which at first consisted of rose spots but later became dark, like that of typhus fever The tongue was thickly coated the cerebration was slow, and he refused food The abdomen was distended He became delirious and 17 days after the rigor which had ushered in the illness he died The pulse averaged from 95 to 100 and the respirations 24 per minute respectively The spleen was easily seen to be enlarged At the necropsy no evidence of enlargement or ulceration of Peyer s patches was found but the greater part of the ileum was in a state of acute inflammation Dr White examined the blood on the fourth day after admission He tried a Widal reaction and obtained clumping with a dilution of 1 in 25 There was no evidence of Eberth s bacillus but one of the forms of bacillus enteritidis had caused the illness In a number of cases hæmorrhage from the bowel had been observed —Dr R TRAVERS SMITH said he had seen two cases which he thought were paratyphoid fever One of them was a woman aged 32 years On admission to hospital her temperature was 103° F her pulse was not markedly quick, there was no diarrhœa or enlarged spleen, and there were no rose spots but there was great abdominal distension and she was rather livid The blood was negative to Widal s reaction She died in about a week and at the necropsy not a trace of disease was found in Peyer s patches neither was the spleen enlarged In the other case the tongue was coated the spleen was a little enlarged, the pulse was rather quick, and the temperature was raised The blood was negative to
Widal s re
days the s
perfectly
proof of it
for —Dr G E P MELDON thought that in paratyphoid fever the diet ought to be regulated as carefully as in
hæmorrhages
resence of a
—Dr E M
FANNIN said that he once had under his care a youth aged 17 years, who suffered from a continued fever the characters and course of which were the same as those of typhoid fever There were no rose spots and no enlargement of the spleen but there was acute laryngitis At that time the Widal reaction was negative Ten days after the temperature had become normal a relapse occurred It presented the features of typhoid fever, the laryngeal symptoms were renewed rose spots appeared and the spleen became palpable The patient became very ill and was removed to hospital Two or three days afterwards symptoms of perforation occurred An operation was performed and a perforated ulcer was discovered The patient did not recover Dr Thompson was satisfied that the ulcer was like an ordinary typhoid one In that case then repeated examinations of the blood had failed to give the Widal reaction The course of the illness resembled typhoid fever and a fatal result occurred after perforation therefore it was possible that some forms of paratyphoid fever could have the definite ulceration of Peyer s patches —Dr KIRKPATRICK said that he would like to ask whether any differentiation had been made in the clinical history of the fevers which were due to the different groups of paratyphoid bacilli —Professor E J McWEENEY discussed the cases from a pathological point of view He said that he would be inclined to describe Dr Parsons s second and third cases as cases of infection with G rtner s bacillus It had been mentioned that the blood serum failed to agglutinate cultures of the typhoid bacillus but agglutinated cultures of Gartner s bacillus That carried an indication of infection with Gartner s bacillus which was not quite the same thing as paratyphoid fever Gartner s bacillus was not quite the same type as the alpha and beta groups of paratyphoid bacilli but presented certain differences It was quite possible that the second and third cases were paratyphoid fever but the bacilli would have had to be isolated and their characters fully te ted What he found lacking in the pathological description was a statement of the different dilutions which were employed —Dr PARSONS in the course of his reply, said that intestinal lesions had been mostly found to be in abeyance during paratyphoid fever and he thought that in it restriction of the patient s diet was not so necessary as in typhoid fever There was no difference in the clinical course of the fevers produced by the alpha and beta groups In his communication he had
ense
and included
was
aware that th
to a
small group of bacilli

Dr G PEACOCKE described the clinical history of two cases of Large White Kidney which had been recently under his care The symptoms of each case were very similar and were briefly anæmia universal dropsy diarrhœa and scanty, highly albuminous urine containing numerous casts —Professor McWEENEY, Dr TRAVERS SMITH and others took part in the ensuing discussion

---

BRITISH GYNÆCOLOGICAL SOCIETY —A meeting of this society was held on Feb 9th, Dr William Alexander the President being in the chair —Dr H Macnaughton Jones read notes of a case of Ascites with Pelvic Symptoms which proved to be due to a typical fibroma of the left ovary the tube was not involved and the adnexa on the opposite side were healthy —Dr Macnaughton Jones also read notes of a case of Carcinoma of the Ovary in which there had been neither pain nor any evidence of malignancy up to within six weeks of the operation which was undertaken for parametritis and peritonitis The tumour (exhibited) was adherent to a myomatous uterus in front and to the intestine and rectum behind, neither tube was involved nor the other ovary There was no ascites —After the discussion on these specimens the President delivered his Inaugural Address embodying his own experience of the rise and progress of gynæcology When he was a student there was no gynæcology worthy of the name The abdomen belonged to the physician and 'inflammation was a name which included many diseases which were now treated successfully by the surgeon or the gynæcologist Abdominal tumours were in the first instance referred to the physician and only when medical measures failed was the case handed over to the operator Whilst the physician treated all the internal diseases of the abdomen the obstetrician repaired any damage caused by parturition But the obstetricians had but small experience in surgery and did not often care to undertake it and so these cases passed into the hands of the general surgeon Gynæcology afterwards learned from medicine the mutual action of the genital organs and the rest of the system, from obstetrics the changes due to pregnancy, but it was to surgery that the greatest advances of the past 50 years were due Surgery and gynæcology had so much in common that a knowledge of the former was necessary for the successful practice of the latter The earlier gynæcologists were not surgeons but were experts in the application of pessaries and many were remembered owing to the instruments bearing their names No examination was considered complete without the use of sound and speculum instruments which bimanual palpation had rendered obsolete save for some specific purpose One of the most serious operations of that day was perineorrhaphy as shown in a report of 12 cases with two deaths Abdominal operations were rarely performed and generally ended fatally Yet the surgery was excellent and some operators, by instinctive surgical cleanliness obtained much success There was, however no guide until Lister enunciated the germ theory of disease The extensive use of carbolic acid followed and worked wonders in general surgery In 1877, when Lister came to London Spencer Wells had reduced his mortality from 25 5 to 9 per cent, with the carbolic spray he got still better results Soon dissatisfaction was expressed at the irritation of the tissues caused by antiseptic dressings Meanwhile bacteriology had developed and hence arose the aseptic system of treating wounds It was asepsis
of Wells Tait Bantock and ot
who without admitting the ger
lighted upon the practice of asep
highest development of the germ theory and by no class of
more successfully
t aseptic surgery
the surgeon more
certainty and greater success The knowledge thus acquired once belonged to a few special men but had now become diffused throughout the country and aseptic

gynæcology was brought, as it were, to the doors of patients. He had been surprised at the excellence of the gynæcological as well as surgical work performed in small hospitals and the valuable assistance that could now be obtained in distant places from men whose surgical instincts were kept fresh and keen in such hospitals. There were other improvements which had accentuated the success of both antiseptic and aseptic gynæcology. Foremost amongst these was the Trendelenburg position in pelvic operations, then the avoidance of post-operative hernia by the methods of closing the abdominal wall, and the value of time in diminishing shock was well understood. Gynæcology still afforded an unexhausted field for future research and effort as long as the present high mortality of cancer of the uterus continued. Again, the nervous diseases of women required further study and the conditions, too often erroneously attributed to neurasthenia or hysteria, required to be classified and their treatment formulated. Their present treatment of uterine displacements could hardly be termed rational; it would not be tolerated in the displacements of other organs. The causes of many forms of displacement were involved in obscurity and urgently required elucidation.

THERAPEUTICAL SOCIETY.—A meeting of this society was held at the Apothecaries' Hall, London, E.C., on Jan. 24th.—Dr. W. E. Dixon (Cambridge) read a paper on the Action of Alcohol on the Heart. He said that alcohol was thought of by some as a stimulant, by others as a depressant, but substances such as thyroid extract, which produced little effect on health, might improve nutrition in disease. The action of alcohol was considered: (1) on the rate of the pulse; (2) on the heart itself; (3) on the blood-vessels; and (4) on the blood pressure. In small quantities and in a concentrated form it decidedly quickened the pulse at first but had no effect if it was much diluted; in very large doses it slowed the pulse. Its quickening action depended on its irritating effects on the mouth and stomach, like that of ammonia or even burnt feathers in fainting, but concentrated alcohol was more powerful than either. In too great a quantity it depressed the medulla. If chloroform was first given the stimulating effect was prevented. The heart was caused to contract more powerfully by alcohol at first though if much chloroform was first administered the heart became fatigued and did not respond to the stimulative power of alcohol. The internal vessels were constricted by the action of alcohol, as might be shown by the oncometer, the arm shrinking in bulk 15 or 20 minutes after it had been taken. This constriction drove the blood to the superficial vessels and caused the flushing of the face. Alcohol increased the blood pressure by stimulating the heart and constricting the vessels. Dr. Dixon summed up his remarks by saying that alcohol in small concentrated doses increased the rate of the pulse and the systole of the heart, constricted the deeper vessels, and increased the blood pressure, especially when the heart's action was feeble; it was therefore of great service in cases of fainting. It much diluted it had little effect on the heart but acted as a food, replacing starch in maintaining the heat of the body. In too large doses it depressed the heart.—Dr. H. A. Caley read a paper on Some Points in the Actions and Uses of Bismuth Salts, referring principally to the three insoluble salts in common use—the subnitrate, salicylate, and carbonate. Their local action on the stomach was first considered, their mechanical, astringent, and antiseptic properties were then discussed, and reasons were adduced for regarding the local action on the mucous membrane as the most important factor, their special usefulness in gastritis and ulcer being emphasised. Of the three, the carbonate was the most generally useful as a gastric sedative. In dealing with the action of bismuth salts in intestinal disorders Dr. Caley brought forward experimental evidence bearing on the antiseptic action of the three salts; the subnitrate had definite germicidal action on cultures of the bacillus coli, the salicylate a similar but much weaker effect, while the carbonate was inert as a germicide. Under laboratory conditions this antiseptic action of the first two salts was destroyed by alkalies; on the other hand, therapeutic experience showed that an alkaline medium did not destroy their efficacy. For this and other reasons it was inferred that the principal action of bismuth in the intestines was a local action on the mucous membrane and that the presence of catarrhal inflammation was one of the chief indications for its employment. If given in sufficiently large doses bismuth was potent in many intestinal disorders and was capable to a large extent of replacing the more direct intestinal antiseptics, strong astringents, and opiates. Of these three salts the subnitrate was the most efficacious in irritant lesions of the intestines and where a more marked astringent effect was desired he preferred a combination of this salt with catechu or other vegetable astringents to the more recently introduced subgallate of bismuth.

LIVERPOOL MEDICAL INSTITUTION.—A pathological meeting of this society was held on Feb. 9th, Dr. James Barr, the President, being in the chair.—Mr. W. Thelwall Thomas and Dr. E. Cleaton Roberts showed two specimens of Multiple Villous Growths of the Bladder removed from patients aged 56 and 60 years.—Mr. Thomas also showed two specimens of Volvulus. One was in a woman, aged 56 years, and included 15 inches of large and three inches of small intestine. The stump had a complete turn from left to right with a gangrenous convexity. The other was in a woman, aged 22 years, in whom 18 inches of gangrenous small intestine were removed. Specimens from a third abdominal case exhibited by Mr. Thomas showed the ovary and Fallopian tube to form the walls of an abscess cavity to which were attached four inches of gangrenous small intestine. These were resected and end-to-end anastomosis was performed.—Mr. J. Douglas-Crawford showed Microscopical Preparations of Actinomycosis from the jaw and from the skin.—Dr. R. J. M. Buchanan showed a Megasphere from a case of carcinoma of the lung.—Dr. Nathan Raw showed specimens of Primary Tuberculosis of the Kidney with Secondary Affection of the Bladder.—Dr. W. Blair Bell showed Radiographs (by Dr. C. Thurston Holland) of a case of Morton's Disease before and after treatment which consisted in the excision of the fourth metatarso-phalangeal joint and had resulted in complete cure.—Dr. Ernest E. Glynn showed a greatly Dilated Œsophagus from a man with symptoms of stomach disease; the necropsy showed, however, that the stomach was contracted and the cause of the dilatation remained obscure; there was no microscopical change in the musculature of the œsophagus.—Dr. Glynn also showed a Thrombosed Pulmonary Artery which had caused death in a boy a few hours after a perfectly successful operation for appendicitis.—Dr. A. W. Campbell read a note on Tuberose Sclerosis of the Brain, a very rare but well-defined condition consisting of a peculiar hard whitish appearance on certain areas of the cortex; these were not raised and did not infiltrate below the level of the immediate white matter. Microscopically they showed a glia structure and branched tubular glandular structures lined by columnar epithelium. Giant nerve cells were also seen. In the kidneys were myo-fibromata and on the skin soft tumours called adenoma sebaceum. The patient was an epileptic idiot, aged 27 years.—Dr. G. G. Stopford Taylor and Dr. F. H. Barendt spoke of having seen this condition of the skin in mentally defective persons and Mr. E. M. Stockdale and Dr. W. B. Warrington discussed the nature of the gland like structures.—Dr. C. Thurstan Holland read a note on the X Ray Diagnosis of Kidney Stones and showed a "Diaphragm Compressor" designed by himself. By the use of such a compressor the movements of the kidney during respiration were controlled, much sharper definition was obtained, and good negatives might be readily produced. By this method the negative diagnosis was made more sure—a point of very great importance. The note was illustrated by a series of lantern slides showing stones in the kidney. One slide showed an oxalate stone which when removed was found to weigh two grains, whilst another slide showed a uric acid calculus which weighed five grains.—Dr. Buchanan gave an account of a Method of Staining the Blood Elements, designed to show a difference in the staining characteristics of the red cells of pernicious anæmia. He also gave an account of the centrosome and attraction sphere of cells.

LARYNGOLOGICAL SOCIETY OF LONDON.—A meeting of this society was held on Feb. 3rd, Mr. Charters J. Symonds, the President, being in the chair.—Mr. C. A. Parker showed a case of Tuberculosis of the Larynx in a woman, aged 31 years. The disease commenced during her fourth pregnancy, since which she had been pregnant five times. On three occasions the child was born alive and on two occasions she had miscarriages.—Mr. H. Clayton Fox showed, for Dr. Frederick Spicer, a case of Diffuse Papilloma of the Vocal Cords; and Dr. Edward Law showed a man, aged 69 years, from whom a Laryngeal Growth was removed 21 years ago from the right vocal cord by the late Dr. Whistler. Views as to the present condition were invited. Some members were of opinion that the case was malignant but the general feeling was that this was not so.—Mr. P. R. W. de Santi showed two cases, the first being that of a woman, aged 39 years, exhibited at the last meeting, with a laryngeal swelling which was thought to be tuberculous but a microscopical slide now showed that it was undoubtedly squamous-celled carcinoma. The second case was that of a man, aged 60 years, with a large mass of Malignant Glands in the Neck and Swelling of the Larynx on the same side.—Mr. Stephen Paget showed three cases for diagnosis. The first was a case of Fixation of the Left Vocal Cord; the opinion of the meeting was that this was due to aneurysm. The second case was one of Growth of the Right Ventricular Band. The third was one of Growth in the Larynx which was generally regarded as [illegible]bers inclined to the view th[illegible]. Steward showed a case of R[illegible]onsils associated with Lymphadenoma in a woman, aged 64 years.—Dr. F. W. Bennett showed a specimen and photographs of a Malignant Growth of the Larynx and a case of Nasal Ulceration of the Septum for diagnosis. The latter was considered to be a case of ethmoiditis.—Dr. Herbert Tilley showed a case of Primary Sore on the Tip of the Tongue in a man, aged 40 years. There was slight enlargement of the glands but no rash. Some doubt was expressed whether it was not a simple granuloma resulting from the irritation of the caustics which the patient had repeatedly applied.—Dr. G. C. Cathcart exhibited two cases, the first being that of a patient shown at a previous meeting, with Pachydermia Laryngis (?) Tuberculous; and the second being a case of Combined Functional and Organic Paresis of the Larynx in a singer, aged 34 years.

Dermatological Society of London.—A meeting of this society was held on Feb. 8th, Dr. J. J. Pringle being in the chair.—Dr. T. Colcott Fox showed (1) a man, aged 50 years, who had lived in India and who, six months after his return to England, had developed a generalised pruriginous eruption all over the body and limbs. There were to be seen small infiltrated obtuse papules situated rather deeply in the skin, showing no grouping and not developing into vesicles. The case resembled both the prurigo of Hebra and the eruption described under the name of pseudo-leukæmic prurigo, but there were no enlarged glands or any signs of lymphadenoma. (2) A man who was suffering from an attack of Ordinary Eczema of the Lumbar Region but in whom were found accidentally, on stripping the back to view the eczema, many large nodes situated deeply in the hypoderm over the last two ribs on the left side. The question was, Were these gummata or some kind of true tumour formation? They had been in existence for six years. The majority of members thought that they were probably gummata.—Dr. Pringle showed a man, aged 64 years, with Extensive Symmetrical Sclerodermia of seven years' duration. The patches extended over almost the whole of the legs below the knee, on the thighs, over the area roughly corresponding to the second lumbar segments according to Head, and from the styloid processes of the ulnæ up to the tips of the olecrana, thus corresponding to the first dorsal nerve areas.—Dr. [illegible] showed a case of Mixed Sclerodermia. [illegible] ago with the appearance of a [illegible] subsequently two more patches appeared in the neighbourhood of this. Two years ago the left arm began to waste and when shown there was extensive sclerodermia with rigidity and partial immobility of the elbow-joint from the contraction of the skin. Most of the patches showed the characteristic ivory-white appearance but in some situations there wa[illegible] Weber showed a [illegible]ted Sarcoma i[illegible] the growths. The usual marked œdema and almost purple colouration of the limb were present.

South-West London Medical Society.—A meeting of this society was held at the Bolingbroke Hospital, Wandsworth Common, on Feb. 8th, Mr. E. F. White, the President, being in the chair.—Mr. G. H. Makins gave an address entitled "Some Remarks on the Indications for, and the Results of, the Operation of Gastrojejunostomy." He observed that as to the choice of operation the two main methods open to the surgeon were the anterior and the posterior operation, the object of either being the provision of an efficient anastomosis with the small intestine to short-circuit the pylorus, the most important technical points being the insurance of an opening of sufficient size and that this should be at the most dependent part of the stomach. What is the most dependent part of the greater curvature? By the aid of diagrams this was shown to be beneath the left rectus muscle. The stages of the operation were then reviewed. In preparing the patient it was desirable to wash out the stomach for two or three days prior to operation but not on the day of operation. The skin should be shaven dry, ether soap rubbed in, and the skin scrubbed lightly with a brush, the soap removed with clean swabs, and ether or turpentine applied. An incision from three and a half inches to four inches long was [illegible] A small incision was [illegible] was then necessary. [illegible] was then made for the piece of jejunum wanted. The two pieces of bowel were then clamped with Doyen's clamps. A simple running suture carried obliquely across was the best as it equalised the tension between the sutures and controlled hæmorrhage. A fine silk suture sufficed. The clamps and plugs having been removed the abdominal wound was closed and collodion applied, and it was then covered with gauze soaked in a mixture of gelatin and salicylic acid to which some formalin (one drachm to an ounce) had been added. Two days' rectal feeding was enough. The dressing was comparatively *nil*. Regurgitant vomiting was the chief after-trouble. The possible explanations were: (1) the intestine had not been attached to the lowest part of the stomach; (2) the mucous membrane was redundant and a valve was formed which prevented the flow from the stomach to the intestine; and (3) the opening was too small. Some regurgitation always took place and usually did no harm. The indications for the operation were: 1. Pyloric obstruction. In pyloric obstruction due to carcinoma it could be done in any case if sufficient room was left by the disease. The condition of the patient was sometimes a bar, and this was where the mortality of the operation came in. The relief was temporary but this objection was much less than the similar objection which might be raised against colotomy. Where there was ulceration of the growth the relief from pain was very great. 2. Cicatricial contraction. Here the operation was sometimes absolutely simple and successful but in other cases it was a troublesome one. 3. Congenital hypertrophic stenosis. In these cases it was not a good operation, the intestine being too thin and tenuous, and the results had been bad. 4. As an operation of expediency. The operation had been widely recommended and practised for gastric dilatation of unknown causation, for simple gastric ulcer, and for gastric and duodenal hæmorrhage. It has been recommended on the grounds of securing physiological rest. By the freer drainage of the gastric contents it was said to relieve pyloric spasm. Again, the ulcerated surface was less irritated; hence there were relief from pain and less chance of hæmorrhage. Cases were quoted to show that some fallacy might exist in the results seen after these operations mainly due to errors of diagnosis and perhaps less commonly to the failure of the operation to perform what was expected of it.

Otological Society of the United Kingdom.—A meeting of this society was held on Feb. 6th, Dr. Thomas Barr, the President, being in the chair.—The President delivered an address in which he spoke at some length on the institution of research work and the formation of a permanent museum in connexion with the society. He said that since the time of Toynbee the pathological anatomy of the ear had not received adequate attention in this country. The pathologist habitually ignored it in the post-mortem room and yet there was probably no part of the body in which a thorough examination was more important in the interest of progress. The thorough examination of the temporal bone and organ of hearing, however, required more time and technical experience than fully occupied otologists could usually command. Moreover, the operative work which they had to perform rendered it perhaps undesirable that they should engage in post-mortem investigations. He therefore suggested that it might be possible to make arrangements by which temporal bones sent by any member of the society might be examined anatomically and pathologically by young men specially interested in otology and possessed of the requisite knowledge for conducting such researches. A permanent museum would be a great addition to the resources of the society, for otology lent itself to the production of anatomical and pathological specimens.—A discussion then took place on Mr. Charles J. Heath's address, entitled "The Restoration of Hearing after Removal of the Drum and Ossicles by a Modification of the Radical Mastoid Operation for Suppurative Ear Disease." This address was delivered before the society on Dec. 5th, 1904, and was published in THE LANCET of Dec. 24th, p. 1767. Several speakers said that the operation described was practically the one already known as Stacke's, or the Schwartze-Stacke, operation.—Mr. Heath, in his reply, said that he had referred to his operation as a modification of Stacke's operation. The only statistics which he could quote were as follows: average duration of treatment before operation, 13 months; average duration of the disease, 15 years; proportion of cases with improved hearing, 84 per cent.—Dr. William Milligan read notes of two cases of Labyrinthine Suppuration recently operated on, with special reference to the path of infection. The patients were males, aged respectively 37 and 46 years. In both of them the duration of the disease was at least 20 years and the result of the treatment was complete recovery.—Dr. Herbert Tilley read notes of a case of Acute Labyrinthine Suppuration in a male patient, the subject of chronic otorrhœa. The radical mastoid operation was performed and recovery followed.—Mr. L. Lawrence showed a patient suffering from Chronic Non-suppurative Middle-ear Disease, in whom a mere touching of either tympanic membrane produced marked and rapidly extending hyperæmia. The condition might be called "urticaria of the drum."—Mr. Arthur H. Cheatle exhibited 250 Temporal Bones obtained from patients at all ages; these bones were sectioned vertically through the antrum and mastoid process.—Mr. Hunter F. Tod read notes of a case of Hernia Cerebri et Cerebelli the result of acute encephalitis. The patient was a boy, aged ten years, in whom acute middle-ear symptoms developed in June, 1904. Schwartze's operation was performed and seven days later the hernia was discovered. Gradual recovery followed and hearing was now normal on the affected side.—Other patients were shown by Mr. Ernest B. Waggett, Mr. Richard Lake, and Dr. H. M. Macnaughton-Jones.

HUNTERIAN SOCIETY.—A clinical meeting of this society was held on Feb. 8th, Dr. F. J. Smith being in the chair.—Dr. Purves Stewart showed a case of Oculomotor Paralysis of the Eye of a woman suffering from tertiary syphilis. She was rapidly recovering under treatment with iodides and mercury but still exhibited divergent strabismus and weakness in the action of the superior, inferior, and internal recti muscles, a dilated pupil, and weakness of accommodation. Ptosis was also present with corrugation of the forehead on the same side, a sign which was not present in hysterical ptosis. The gummatous process probably affected the nerve at the point at which it pierced the dura mater.—Dr. Stewart also showed a case of Cervical Sympathetic Paralysis due to division of the second and third dorsal roots on the right side by a Mauser bullet in the Boer war. The pupil was contracted on the same side and did not dilate on shading from light or pinching the lobule of the ear. The eye was sunken into the orbit owing to paralysis of Müller's muscle. There was ptosis to a slight degree on the same side for the plain muscle fibres in the upper lid were paralysed. The area of sweat fibres supplied by the cervical sympathetic had been marked out on this man and had been found to be the exact half of the head and neck, the front of the chest as low as the nipple and the back as far down as the lower angle of the scapula and the whole of the upper limb. The man was induced to sweat. Then charcoal was puffed over him and adhered to the sweating area. The area of paralysis was dry and the charcoal did not adhere. The patient was then photographed and these photographs were shown to the meeting. Photographs exhibiting spasm of the sympathetic from a case of Graves's disease were also exhibited for contrast.—Dr. Smith, Dr. W. Langdon Brown, Dr. R. Hingston Fox, and Mr. Harold L. Barnard took part in the discussion of the cases.

ROYAL MEDICAL SOCIETY, EDINBURGH.—A meeting of this society was held on Feb. 10th.—Dr. F. W. N. Haultain read a paper on Fibroid of the Uterus. He said that he divided fibroids into two classes—those which gave rise to symptoms and those which did not—and he stated that the condition was more common than one suspected, for probably one in every five women was affected, though the proportion of cases in which the growth became malignant was infinitesimal. In the course of his remarks he considered the question of operative interference in cases where there were inconvenient symptoms and he stated that it was his opinion that the operation should be performed in all such cases when the patient was young and that the approach of the menopause was a contra-indication. He continued by discussing the kind of operation to be performed and stated that he was in favour of suprapubic hysterectomy. Dr. Haultain concluded by giving an account of the clinical and pathological aspects of some of his own cases. During the course of his paper he exhibited some interesting specimens.—Dr. A. C. Geddes moved, and Mr. J. D. Wells seconded, a vote of thanks.—Dr. H. N. Fletcher read a dissertation by Dr. Matthews on Tuberculous Peritonitis.

BRISTOL MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Feb. 8th, Dr. Reginald Eager being in the chair.—Mr. H. F. Mole showed the following patients and read notes of their cases: (1) an infant operated on for Spina Bifida at 14 days old; (2) a case of Ruptured Intestine; (3) a case of Colectomy, &c., for Carcinoma of the Colon; and (4) a case of Excision of the Wrist for Tuberculous Disease.—Dr. J. J. S. Lucas showed (1) a case of Recovery from Tuberculous Meningitis; (2) a case of Exophthalmic Goitre in a man with Glycosuria; and (3) a speciman of Congenital Malformation of the Intestine.—Dr. J. M. Fortescue-Brickdale showed a specimen of Congenital Dilatation of the Ureter and Cystic Kidneys in a child.—Dr. Theodore Fisher showed a specimen of Chloroma of the Dura Mater, and Dr. J. E. Shaw read the clinical notes of the case.—The cases and specimens were discussed by a number of the members present.

PATHOLOGICAL SOCIETY OF MANCHESTER.—A meeting of this society was held on Feb. 8th, Dr. T. Harris being in the chair.—Mr. A. J. Rodocanachi showed a Vesical Calculus which he had removed by vaginal lithotomy. It had been deposited upon a vulcanite button with which someone had plugged a vesico-vaginal fistula following hysterectomy and had been forming for over two years.—Dr. Nathan Raw showed specimens of Lymphosarcoma of the Lungs. Dr. W. J. S. Bythell and Dr. D. Orr gave a lantern demonstration of Colour Photography as applied to Pathological Histology.—Other specimens were shown as card specimens.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held at the Royal Kent Dispensary, Greenwich-road, S.E., on Feb. 3rd, Mr. G. Chisholm Williams, the President, occupying the chair.—Mr. Charles H. Evans of West Norwood and Dr. A. E. Jerman of Erith were duly elected members of the society.—Mr. E. G. Annis, medical officer of the borough of Greenwich, read a paper on Immunity against Disease.

Reviews and Notices of Books.

A Text-book of Clinical Diagnosis by Laboratory Methods. By L. NAPOLEON BOSTON, Director of the Clinical Laboratories, Medico-Chirurgical College, Philadelphia. With 320 illustrations, many in colours. London and Philadelphia: W. B. Saunders and Co. 1905. Pp. 549. Price 18s. net.

THE title on the back of this work hardly conveys an exact idea of its contents, although its sub-title might. It deals chiefly with microscopical and chemical methods applied to the study of disease and there is nothing about auscultation, percussion, or other physical methods of this kind. To some readers the introductory chapter on the Use of the Microscope might seem almost unnecessary but of this we need not complain, for some practitioners to whom this work will prove of great value may find the hints regarding the method of using, cleaning, and observing with immersion lenses very useful.

About 150 pages are devoted to the blood under the following heads: tests for its recognition, estimation of its volume, the histology of fresh blood, its bacteriology and the study of fixed and stained films, special pathology, and the parasitic diseases affecting it The more recent methods for examining and staining blood are fully and carefully described and the subject is illustrated by many original drawings, all of them of great beauty and accuracy Anyone by following the excellent descriptions could soon make himself master of the subject Amongst the coloured plates are those on the blood corpuscles of various animals erythrocytes in various diseases, and the blood in pernicious anæmia, chlorosis, and myelogenic, lymphatic, and spleno medullary leukæmia Cryoscopy is also introduced This is a method which may come to play an important part in the diagnosis and the prognosis of some renal diseases Every method of clinical value for the study of the blood is fully given and with a wealth of illustration not common in some clinical manuals The importance of serum diagnosis is emphasised and its methods are fully set forth The protozoan parasites which invade the blood of the lower animals are described together with the malarial parasite, of which a particularly full account is given, illustrated by many figures in the text and also by coloured plates The various changes of the blood—in its corpuscles and fluid part—in acute infectious and other diseases are all carefully described and a comprehensive account is given of the parasitic diseases affecting the blood

To the urine 240 pages are given and here again there is the same wealth of illustration by means of figures and coloured plates Some of the woodcuts might be omitted—e g , that of a nest of beakers—and the same remark applies in some other chapters This subject is set forth under the following heads physical, chemical, and microscopical In addition to a full account of the method used the significance of the facts observed in relation to disease is stated The influence of some drugs on the excretion of the urinary constituents is given A rather larger chapter than usual is devoted to the sulphates—constituents of the urine which clinicians sometimes are likely to neglect Seeing that the sulphur excreted has an intimate relation to proteid metabolism it deserves careful consideration and estimation The loosely combined sulphur in the urine is a factor many chemists regard as a pre eminent feature which distinguishes Bence Jones albumose from the digestive albumoses as well as from histon and globin The author gives his own method for its estimation (p 188) The xanthin and purin bodies are now beginning to attract more attention and are dealt with accordingly In describing the detection and the estimation of proteids the author sets forth his own method for applying the old nitric acid test (p 207) In this connexion, he says, he has "found but two reagents that are capable of withstanding the tests necessary to render them worthy of special clinical mention—viz , concentrated nitric acid and the nitro-magnesium mixture of (Sir William) Roberts, which is composed of nitric acid two parts and saturated magnesium sulphate solution ten parts' There is a surprisingly realistic drawing on Plate 14 showing Fehling s test, the manner of conducting it, and the precipitate of the red cuprous oxide, besides which tests for glucose, lactose and the tests for the pentoses are given Oliver s peptone test for bile salts (p 240) is cited as one of the most delicate and trustworthy for the detection of bile acids in the urine The value and the significance of the diazo reaction are fully discussed

The subject of gastric contents occupies about 50 pages As to the detection of free hydrochloric acid dimethylamido azobenzol is placed first as the most sensitive reagent and is followed by phloroglucin vanillin, while Töpfer s method for its estimation is given as "sufficiently accurate for practical laboratory studies" A full account is given of the fæces, more particularly of their fauna and flora, both of which are extensive The organisms found are well illustrated by many figures The sputum, buccal and nasal secretions, discharges from the ear, the eye, and the genital organs, the synovial and cerebro spinal fluid, and milk are successively dealt with and with equal fulness and lucidity An unusual amount of space and fulness of treatment are given to the subject of transudates and exudates and to the parasitic diseases of the skin

This work is compact, trustworthy, comprehensive, and well illustrated, and we most cordially commend it as a serviceable and practical treatise on the subjects with which it deals Nothing has been spared in the way of illustration which could help to make it both useful and attractive

---

Surgical Diseases of the Abdomen with Special Reference to Diagnosis By RICHARD DOUGLAS, M D , formerly Professor of Gynæcology and Abdominal Surgery, Medical Department, Vanderbilt University, &c Illustrated with 20 full page plates London Rebman, Limited 1903 Pp 883 Price 30*s* net

THE importance of abdominal surgery at the present day can hardly be overestimated A large proportion of the major operations performed now deal with this cavity and its contents and some of the greatest recent advances in surgical knowledge and treatment have reference to the viscera of the abdomen The volume under review deals but briefly with operative technique but is devoted chiefly to the question of diagnosis, which is of paramount importance, for the treatment cannot be determined satisfactorily until the diagnosis is made There is no small risk nowadays of the diagnostic art losing much of its value from the tendency which exists to postpone the diagnosis until an exploratory laparotomy has been performed This course is no doubt sometimes necessary, for the diagnostic signs may be too few and too obscure to allow a diagnosis to be made but the too ready recourse to abdominal section cannot fail to discredit operation in the eyes of the lay public who hardly recognise the difference between an operation for diagnostic purposes and one for treatment Dr Douglas s work is therefore especially valuable in that it devotes a large proportion of its space to the question of diagnosis We have perused the book with much pleasure, for it is representative of modern surgery and though the therapeutic sections are brief, yet we frequently find useful and valuable notes in them We may quote the recommendation that when irrigation of the abdominal cavity has been employed in peritonitis it is well to leave the abdomen full of saline solution, for the author tells us that it relieves shock, allays thirst, and tends to prevent post operative adhesions Each chapter is followed by a list of the recent works and articles on the subject and this should prove of great assistance to the reader The author is evidently well acquainted with current literature and his views seem to be sound The work can be recommended as containing an accurate account of the surgical diseases of the abdomen, especially from the point of view of diagnosis

---

Diseases of the Ear, for Practitioners and Students of Medicine By JAMES KERR LOVE, M D Glasg , Aural Surgeon, Glasgow Royal Infirmary , Lecturer in Aural Surgery, St Mungo s College Glasgow , Aurist to the Glasgow Institution for the Education of the Deaf and Dumb Bristol John Wright and Co , London Simpkin Marshall, Hamilton, Kent, and Co , Limited 1904 Pp 339 with 54 photographs, two coloured plates, and many illustrations Price 25*s*

Dr Love tells us in the preface to this large and elegant book that his chief object is to spread a sense of the responsibilities which the modern treatment of suppurative diseases of the ear has thrown on the general practitioner and on the aural surgeon He has therefore devoted a large proportion of his work to this subject forms of piroplasma bovis, showing films prepared from affected animals in various parts of Ireland, and he also showed actual specimens of the varieties of ticks which are the intermediate hosts and the source of contagion from one beast to another. Medicinal and other curative treatments are entered into fully both by the author and by those who joined in the discussion. In the paper on the Selection and Purchase of Army Horses Mr. Hunting deals with what he considers to be the proper ages of horses at time of purchase in peace and in time of war. He discusses the questions of Government assistance to the breeder by contribution and subsidy, and he concludes his paper by a few words on the transport of animals across the sea. In the discussion which followed the paper the methods which were adopted during the recent war came in for a good deal of criticism, it being universally agreed that the way in which horseflesh was purchased and wasted cost the taxpayers of the country many hundreds of thousands of pounds unnecessarily.

JOURNALS AND MAGAZINES.

Ophthalmology. Vol. I., No. 2. January, 1905. Published by H. V. WURDEMANN, M.D., and NELSON MILES BLACK, M.D., of Milwaukee, aided by a large editorial staff. Publishing office: 105, Grand Avenue, Milwaukee, Wis., U.S.A. A quarterly journal, price per number, 6*s.*—The original articles in this number of *Ophthalmology* are six. 1. On Congenital Word-blindness, by William Evans Bruner, M.D. 2. Binocular Fixation and the Hypothesis of the Dominant Eye, by Percy H. Friedenberg, M.D. 3. Cases of Retinal Separation, by Allen Greenwood, M.D. 4. Report of Comparative Tests of Coloured Glass used in Railway Signalling, by Nelson Miles Black, M.D. 5. Improved Series of Wools for the Detection of Subnormal Colour Perception, "Colour Blindness," by Charles A. Oliver, M.D. 6. The Medico-legal Relations of Ocular Injuries, Pensions, and Insurance Rates, and a Reference to a Scientific Plan for estimating the Loss of Earning Ability, by H. V. Würdemann, M.D. In addition there are numerous abstracts from current ophthalmic literature and reviews of books.

The Ophthalmoscope. Editors: SYDNEY STEPHENSON (London) and CHARLES OLIVER (Philadelphia); sub-editor, C. DEVEREUX MARSHALL (London). London: George Pulman. Vol. III., No. 2. February, 1905. Price 1*s.*—This number contains three original articles on the Use of the Magnet in Ophthalmic Surgery. The articles are written by Professor J. Hirschberg, Professor O. Haab, and Mr. S. Snell and are all of considerable interest. They are briefly noticed in another column. A section of the review is devoted to current ophthalmological literature and another to reviews of recent works.

Looking Back.

FROM
THE LANCET, *SATURDAY*, Feb. 17, 1827.

A NEW ELECTRICAL DISCOVERY BY MR. EARLE.

We cannot sufficiently express our satisfaction at being the organ of exclusive communication of a novel and brilliant mechanical discovery of Mr. Earle; our gratification is not the less unalloyed by an anticipation of the extreme chagrin and mortification *Roderick* of the Yellow will experience on a perusal of the following "doings" of his staunch contributor. The case has been extracted from our note book earlier than usual, from the idea, that as spring is rapidly approaching, and all the *world about to physic*, it is highly necessary to know that a morning walk to Mr. Beaume the electrician, is now discovered to be a very genteel and speedy mode of gaining that end, and at the same time of keeping the stomach and mucous membranes intact from their vulgar noisy griping acquaintances, senna and salts. In anticipation of the future fame and gratitude attached to Mr. Beaume's galvanic efforts, we may suggest de Vie as not an inappropriate addition to his already respected name. Beaume de Vie, alias Compound Decoction of Aloes. Such appendage would proclaim at once his calling, and the world's gratitude.

Mr. Earle has had under his care, for a considerable time, a child affected with amaurosis. Its bowels have been constipated; their secretions of a very offensive character; and the biliary secretions, as might be expected, of an unhealthy appearance. The disease of the eyes has been regarded as sympathetic, and the grand sourse of mischief referred to the hepatic organs. Accordingly, mercury has been the grand anchor of hope; calomel, with its irritating step-sister, scammony, has been prescribed without any regard to frequency or quantity. Mr. Earle, at each successive visit, has expressed surprise at *finding no amendment in the biliary secretions*, after the employment of such active medicines. The sovereign remedy was ordered to be followed up with greater vigour, until a healthy action could be induced. But the child's liver was incorrigible, and not to be bullied even by such powerful means. Desparing of success from their further use, the idea of electricity flashed upon his recollection; and forthwith, the liver was electrified. It has been so again and again, but without the wished-for change. If Mr. Earle had himself possessed a little more of the "electrical devil," he would soon have discovered that the continuance of the hepatic derangement was more attributable to the negligence of the dresser, than to the obstinacy of the organ in question. The medicines prescribed, from the commencement were neglected being written for by the dresser, and the child TOOK ABSOLUTELY NOTHING. If Mr. Earle had electrified the *brain of his dresser*, he would have exhibited himself more favourably as a shrewd and attentive hospital surgeon.

NOTICES TO CORRESPONDENTS.

The complaints of a "FRIEND" respecting occasional errors in orthography, are not in some respects devoid of foundation. If he were acquainted with the nature of the evil to be overcome, his excellent judgment would furnish many excuses for that which now appears to be the effect of negligence. As to the *cover*, we take no part in its management, and never see it until the Number is published—this department rests entirely with the Printer.

JEMMY COPLAND says that we cannot *decline* a noun; at all events we have *declined his articles.*

New Inventions.

A NEW FORM OF THIMBLE.

A NOVELTY lately introduced under the name of "Turner's open thimble" seems to present some useful features. It differs from the ordinary form of thimble in having a portion (rather less than one-half) of the side cut away, as shown in Fig. 1, so that even prolonged use of the thimble is not attended with any compression of the finger-tip and nail. When on the finger the thimble is turned to some extent sideways in such a manner that the outer edge of the nail—i.e., the edge furthest from the thumb—is visible in the centre of the open part. The usual form of the open thimble is as shown in Fig. 1, but it is also made with the top cut off, as shown in Fig. 2. The makers (supplying wholesale firms only) are Messrs. W. Turner and Co., 3, Batavia-buildings, Hackins Hey, Liverpool.

The Hunterian Oration

THE name of JOHN HUNTER can never be forgotten His services to surgery were so great that we need no Hunterian Oration to remind us of all that he has done and of all that he was Yet the delivery of such an oration as that of last Tuesday cannot but help us to appreciate more fully to estimate more highly, the character of the man and the work which he accomplished We have listened to many Hunterian Orations and we have valued the eloquence of the orators but we have never been privileged to listen to a Hunterian Oration which contained a more just appreciation of its subject To devote an hour to mere eulogies of JOHN HUNTER is futile, indeed no one would have disliked them more than JOHN HUNTER himself But to occupy the time in pointing out the way in which HUNTER accomplished all he did, to show how he spent his time, his money and even his life itself in the advancement of knowledge and the attainment of progress, is quite another and a much more appropriate method, and this was the method adopted by the most recent orator, Mr JOHN TWEEDY President of the Royal College of Surgeons of England

To understand JOHN HUNTER'S life three things are necessary We must first realise the parlous state of the study of anatomy in England in the middle of the eighteenth century In 1746 WILLIAM HUNTER, JOHN'S elder brother, had commenced the systematic instruction of anatomy, with dissections, for a society of naval surgeons and this was indeed the starting point of the true study of anatomy in this country The successful practice of medicine and surgery is unattainable without an exact knowledge of the structure of the human body and for this dissection is essential While the prejudice against dissection was strong, as in the Middle Ages it was impossible for teachers of anatomy to obtain the material which they needed for dissection this prejudice had in some degree abated when WILLIAM HUNTER established his school of anatomy and surgery but to a certain extent this unreasonable prejudice against dissection exists even now, *for many boards* of guardians decline to permit the unclaimed bodies of paupers dying in their infirmaries to be used for anatomical purposes JOHN HUNTER profited greatly by being introduced early into the progressive school of his brother and this doubtless had much to do in training and fitting him for his future work But Mr TWEEDY shows that there was a second cause for JOHN HUNTER'S extensive contributions to surgery Most of the work of his predecessors was empirical, it was based chiefly on the precedent of previous cases, while of pathology, as affording working theories, there was almost none HUNTER saw that disease could not be treated satisfactorily without a knowledge of the morbid processes and to obtain that knowledge he strove persistently He recognised that for the attainment of this knowledge of pathology careful observation was needed of the products of disease and for that reason he set about the formation of a museum From the first he saw the need of not limiting the study of anatomy and pathology to the human body He felt that man was so near akin to the lower animals that the study of the vital and the morbid processes of the one must assist in the investigation of the life processes and the diseases of the other therefore his museum included numerous dissections and examples of the organs of birds, beasts, and fishes The museum of the Royal College of Surgeons of England, as the present representative of HUNTER'S museum contains one of the most elaborate collections in the world in illustration of the physiology of animals and plants

There was a third factor which assisted JOHN HUNTER greatly in the prosecution of his task All the time during which he was carrying on his extensive and numerous investigations he was in the active practice of his profession This always suggested to him the application of the facts which he elicited in his researches and thus he possessed a touchstone on which he could try the theories suggested by his facts which explains the splendidly practical nature of his work There may have been greater surgeons better pathologists and more erudite anatomists than HUNTER but it may safely be said that never in the whole history of medicine has there been a man who devoted himself more thoroughly and more intensely to the advancement of the medical sciences His influence was great in his own day and from that time to this can be traced in the work of his immediate pupils—ABERNETHY, CLINE, ASTLEY COOPER and JENNER At the present time his work is still bearing fruit and his museum enlarged and extended is of the greatest value in the advancement of medicine and surgery So will it be in the future To few is it given to accomplish so much work while living and to leave behind so vital an effect on the science of succeeding ages, and the reasons why HUNTER will receive the lasting regard of the world are well revealed in Mr TWEEDY'S eloquent oration, which we publish this week

◆

The Claims of Sociology.

UNDER the modest title of "Sociological Papers,' the recently constituted Sociological Society has just issued what might perhaps be better described as a first volume of 'Transactions containing presumably only a selection from the essays read at its meetings, with reports of the debates and with written contributions to those debates from absent members to whom advance proofs of the essays had been furnished At one of the meetings the chair was taken by Professor KARL PEARSON who opened a discussion by declaring that he was not a member of the society and that he was sceptical of its power to do effective work, a declaration which ultimately called forth a reply several pages in length from the secretary, Mr BRANFORD, but with which nevertheless, we are disposed to think that most readers of the volume will be likely to agree It may be admitted that the course of social organisation must be subject to laws which would be ascertainable if they were rightly sought for; but the efforts hitherto made in this direction have not been conspicuously successful. In 1857 a body called the National Association for the Promotion of Social Science was founded under the auspices of the first Lord BROUGHAM who was said to have been greatly pleased at the "wide and indefinite area" over which its labours were designed to extend. This area was, indeed, so indefinite that the first volume of the Transactions contained a paper by a member of the House of Commons, in which, as a remedy for most of the domestic evils afflicting the lower classes of the labouring population, he gravely proposed that pleasant modulation of the voice should be systematically taught in elementary schools for girls, in order that their future husbands, returning tired from work, should be soothed by the gentle tones of their helpmates and should no longer be subjected to the shrill accents of the scold. For several years the annual meeting of this association was held to be an event of some importance; but its useful work was gradually smothered under a weight of superincumbent trivialities and, after a vain effort to obtain new blood by amalgamation with a society for amendment of the law, it perished from an atrophy mainly dependent upon the unfitness of its nutriment to sustain the vastness of its aims. The new society must to some extent be regarded as its successor and we doubt whether its history is likely to be more fortunate.

The general character of the contributions contained in the volume before us is one of vagueness, arising partly from an absence of sufficiently definite ideas, and partly from an incapacity for expressing them, the latter perhaps sometimes arising from the circumstance that several of the contributors have foreign names, with a consequent probability either that they have written in what was to them a foreign language or that their compositions have been but imperfectly translated. Whatever may be the explanation, we find a general clumsiness of the sentences, a frequent employment of common words in strained or unnatural meanings, and an obscurity of construction which a few well-employed prepositions and conjunctions would have done much to obviate. It is none the less noteworthy that the gentlemen reading papers, and the gentlemen (or ladies) sustaining the discussions, appear to have been profoundly convinced of the importance of their several contributions to the stock of human knowledge; moreover their politeness to one another can only be described as exemplary. It would be difficult to read the reports without some recollection of the historical society described by the poet:—

> "Where, ladling butter from alternate tubs,
> Stubbs butters Freeman, Freeman butters Stubbs."

If proceedings thus conducted are not likely to lead to discoveries of importance, it is at least tolerably certain that they will be sources of harmless pleasure to the great majority of the learned or unlearned persons concerned in them. An important discussion as to which an exception must be made, and which, moreover, was calculated to be of great interest to the medical profession, arose out of the reading of Mr. FRANCIS GALTON'S paper on Eugenics. This paper was so fully referred to when first issued as a "proof under revision," in a leading article in THE LANCET of May 14th, 1904, and has since been so often reproduced in entire or in abbreviated form, that it can hardly be other than familiar to our readers. We need only remind them that its object was to advocate such a system of controlling the reproduction of the human species that the useful classes of the community should contribute more than their proportion to the next generation. The results anticipated by the author are that it might be possible to raise the average quality of our nation to that of its better moiety at the present day. If this could be done, he thinks that "the general tone of domestic, social, and political life would be higher. The race as a whole would be less foolish, less frivolous, less excitable and politically more provident than now. Its demagogues who played to the gallery would play to a more sensible gallery than at present. Men of an order of ability which is now very rare would become more frequent, because the level out of which they rose would itself have risen."

These be brave words and Mr. GALTON'S belief in the possibility of realising what they imply depends upon his corresponding belief in an habitual inheritance by children of the good qualities of their parents. In the very short speech with which he closed the discussion, he said that "much which had been urged against this view might have been appropriately said 40 years ago, before accurate measurement of the statistical effects of heredity had been commenced, but that it was quite obsolete now." As evidence in support of his view he gives, in the volume under consideration, an "Index to the Achievements of near Kinsfolk of some of the Fellows of the Royal Society," the "some" including but eight persons, of whom only one, or at most two, could be described as of the highest eminence. It is scarcely invidious to point out that, even in the Royal Society, there are Fellows and Fellows; but it is more practically important to scrutinise the achievements in question, the great majority of which appear to us to resolve themselves into the capable discharge of duty in positions certainly responsible, but for the attainment of which the persons referred to have enjoyed exceptional facilities dependent upon the social or financial positions of their respective families. We do not regard the existing knowledge of the operation of hereditary influences as being sufficient either to justify the enunciation of general laws or to afford any adequate guidance for the regulation of marriages; and we believe it would be as easy to compile an imposing list of the achievements of persons who are not related to Fellows of the Royal Society as of those who are. What is commonly called an inheritance of genius might often be more correctly expressed as an inheritance of advantages by which a very moderate amount of genius was afforded exceptional opportunities for displaying itself. We expressed last May our doubt whether any science of Eugenics was really in existence, and this doubt has not yet been dispelled. So far as we know, attempts in the indicated direction have not been conspicuously successful in practice. Among the queer so-called "religious" sects now or formerly existing in America, and which were so graphically described by the late Mr. HEPWORTH DIXON, there was at least one in which intended parents were specially selected for pairing by the elders, with a definite view to the production of offspring capable of guiding the affairs of the community to a successful issue. We do not know whether the community in question still exists as an organised body but we have heard that it never produced a single individual of conspicuous ability.

The Indian Medical Service.

We have received from time to time communications from officers of the Indian Medical Service, and from some members of the subordinate medical service who are finding employment in civil hospitals all over India, in regard to various points in the existing medical system of the Empire in which they are severally or mutually interested. The present and the future standing of both services and the relationship of the officers one to another are now much under discussion, and the aspirations entertained by many of the more able and ambitious members of the subordinate medical department will certainly serve to keep these topics from neglect. Not so long ago the difficulties were only in prospect and could not be said to be of an urgent kind, so that it seemed to us more expedient to leave the whole situation to mature, when in process of time it might present features which could be more opportunely and usefully discussed. This has now happened and comment seems to us to be called for. Great changes have been taking place in matters of Indian administration generally and in the growth, spread, and development of Indian medical education. Proof of this has been manifested in our columns but some of the correspondence upon these and cognate matters which has reached us has been dictated by feelings that are of a personal or a purely controversial nature and therefore lacking in sympathy with the best interests of both the public medical services and the medical requirements of India. And so the points thus raised may, it seems to us, be usefully discussed at the present time, if only that a most difficult matter may be removed from the sphere of personalities to that of general policy.

Commissioned medical officers of the Indian Medical Service, as everybody knows, are employed extensively as professors at the large medical colleges of the Empire and give instruction at the great hospitals—those of Madras, Calcutta, and Bombay for example. This for a long time past has always been the case. The consequence is that there are now in India large and increasing numbers of really good medical men belonging to Eurasian and native classes who have been thoroughly educated up to European standards. A reference to some of the papers set for the degree examinations of Calcutta, Bombay, and Madras will remove any doubt that may exist as to the rigour of the qualifying tests. These graduates are, as we have said, chiefly employed as subordinates in the civil hospitals all over India and surgical operations of every kind, major as well as minor, are continually being successfully performed by them. Officers of the Indian Medical Service are not alone in their appreciation of the professional value of the work so done, for it is recognised also by Collectors and magistrates of districts and all classes of the native population. The result is that the Government of India is now, or is fast becoming, fairly well supplied with a highly trained body of servants who, so far as professional qualifications are concerned, are capable of undertaking at less expensive rates of pay most of the duties of the commissioned officers of the Indian Medical Service. Indeed, one of our correspondents goes so far as to forecast what, in his opinion, is likely to be in store for the latter service. He expresses his belief that the policy of the rulers of India towards the Indian Medical Service is based upon the principle of utilising the Service mainly in creating for the Government a sufficiently large and efficient number of subordinate medical servants, recruited from the Eurasian and native classes of India. And in support of this view he adds that such a movement while opening an outlet to the present clamour of the intelligent native who desires Government employment for his educated intelligence might at the same time ease the country of a portion of its expensive administration. The Indian Government, he points out, does, moreover, now occasionally employ such medical subordinates to look after the whole medical and sanitary business of large districts containing no inconsiderable European population when there happens to be no commissioned medical officer available for the purpose. Such a letter as that from which we are quoting expresses the spirit of toleration and generosity which all medical men of a right understanding must feel towards their professional brethren. It is not logical—to say nothing stronger—that we should spare no pains to educate the Indian and, at the same time, should refuse him for ever the opportunities of a free exercise of the talents that we have enabled him to cultivate. But the time when a more liberal scheme can be adopted by the Indian Government is delicate to fix—those who know least the difficulties are clearest as to the absolute necessity for immediate reform and most unable to see how valuable it is for future peaceful developments that the change should come so gradually as to appear a merely inevitable process of social evolution. And in considering the question of the increased employment, and the employment in more responsible and highly placed duties, of the native medical graduates we must not ignore the influence which the difference of race introduces into it—not merely those of a physical nature but racial distinctions of character, religion, education, and methods of thought which, however much we may regret their existence, nevertheless tend to keep the European and the native races of India more or less apart. Nor is it the case that the natives of India do not themselves fully recognise these distinctions. It is a topic upon which we would prefer not to enter but so long as human nature is what it is it cannot be ignored. That in respect of trustworthiness of character there are among the members of the subordinate medical service quite a number of unimpeachable servants will be admitted but that the ethical standards of the native and the European are identical cannot be maintained. The native of India, notwithstanding all his confidence in the British character, has profound confidence in himself and is firmly convinced that either he or one of his compatriots is eminently fitted to administer the business of any official post in India. Ask the same native, however, when he is very ill whether he would prefer treatment at the hands of a compatriot or of an officer of the Indian Medical Service and his preference will be immediate and flattering to our race.

Reviewing the whole situation, we believe that it is a misapprehension to consider that the policy of the Government of India is eventually to displace the European commissioned medical officer in favour of qualified natives or Eurasians. It is certainly not that of the Collector or magistrate, who would strenuously oppose it. Europeans in power in India have naturally enough not the least desire to have either themselves or their families medically treated by either natives or Eurasians instead of by their own countrymen. The education and training of natives of India to be qualified medical men are generally regarded as being among the highest and noblest functions of the Indian Medical Service, so that these men may gradually displace the ignorant "hakedu" and "baid" in ministering to the medical wants of the millions of suffering poor. But it goes without saying that Europeans serving in India will always prefer medical men of their own race. The gradual increase of qualified natives in the towns and the villages has certainly, and very naturally, the effect of diminishing the emoluments from private practice of the officers of the Indian Medical Service, for the former accept much lower fees than the latter and have the advantage of speaking the native languages fluently and of permanency of residence. We consider that it is a legitimate grievance of the qualified natives of India—for it must not be forgotten that it is their country over which we rule—that they are not placed more frequently in medical charge of the smaller districts of India. Whilst the British "raj" lasts, however, in India European medical officers will be required for the larger stations and more important appointments. It would not be for the advance of medical science in India were it otherwise.

Annotations.

"Ne quid nimis."

THE KING'S SPEECH.

THE King, accompanied by the Queen, opened Parliament in person on Tuesday last. The King's Speech made no allusion to any existing position of affairs or pending legislation of especial medical interest, but its whole quiet confident tone showed that in the opinion of His Majesty's advisers the condition of the country is prosperous and the outlook peaceful. We have so often been told that our trade is going or gone and that we are politically isolated and are living on the edge of war that it can only be good for our nerves, as a nation, to feel that those who ought to know best are not afraid to be both happy and hopeful. Among measures of medical interest we note that legislation is promised dealing with alien immigration, the problem of the unemployed, the compensation of workmen, and the adulteration of butter, but we observe regretfully that nothing is said about legislation with respect to re-vaccination.

THE MACLOGHLIN SCHOLARSHIPS.

Mrs. Macloghlin of Southport has decided to found and to endow some scholarships in memory of her husband, the late Edward Percy Plantagenet Macloghlin, M.R.C.S. Eng., and she has offered to the Royal College of Surgeons of England the trusteeship of the fund. The Council of the College has accepted the trusteeship and will invest and administer the £10,000 which Mrs. Macloghlin will bequeath to it, free of legacy duty. The late Mr. Macloghlin received his medical education at University College, Liverpool, where he gained a number of distinctions, among which may be mentioned the Bligh gold medal in anatomy and physiology and silver medals in medical jurisprudence and toxicology and in pathology. In 1884 he became a Member of the Royal College of Surgeons of England and for several years he practised in Wigan but in consequence of ill health he retired from practice and he died in April, 1904, at Southport. In the early part of his career Mr. Macloghlin was hampered by want of means and it was only by his own exertions that he was able to obtain funds for his education. In later life he did not forget these early difficulties and when success came to him the recollection of his own troubles during his studentship suggested to him the idea of founding a scholarship at the Royal College of Surgeons of England with the object of assisting young medical students in real need of financial help to proceed with their studies. Now that Mr. Macloghlin has died Mrs. Macloghlin offers, in accordance with the wish of her husband, to devote £10,000 to carry out this object. It is thought that when invested an income of about £300 will be available and five scholarships are to be founded, the first to be awarded in the first year succeeding the investment of the fund and another in each of the next four ensuing years, so that afterwards one scholarship will be awarded every year. The scholars are to be young men, between the ages of 16 and 22 years, studying and seeking to qualify themselves as Members of the Royal College of Surgeons of England. No student will be allowed to compete for a scholarship unless he is nominated by the Council, which will act on the recommendation of certain persons, provided that the student's conduct has been satisfactory and that he is in need of financial assistance in the prosecution of his studies. The candidates so nominated will be required to enter for the first professional examination for the diploma of Member of the Royal College of Surgeons of England and the scholarship is to be awarded to the candidate passing the best examination. It is intended that chemistry and physics should form the test subjects of the examination. The endowments for the assistance of medical students in London will be materially increased in importance by this very generous gift of Mrs. Macloghlin and we think that no fitter body for the administration of the fund could have been chosen. The yearly amount of each scholarship will be about £60. The total for five years receivable by one student will be £300 and this should prove of very real assistance to many. The struggles which no small number of medical students undergo while working to obtain a qualification are hardly realised even by their more fortunate brethren and not at all by the public. Such assistance as will be afforded by this fund will be of great value.

THE INTRUSION OF THE LAYMAN INTO MEDICAL PRACTICE.

UNDER this title we note a letter from Mr. E. Shenton in the January number of *Medical Electrology and Radiology* in which he states that he had been asked to attend at a patient's house in order to take a skiagram of a case of suspected mediastinal tumour but that the appointment was cancelled at the last moment because a well-known firm of chemists and surgical instrument makers were willing to undertake the case at a lower fee. That the firm in question do undertake x ray work seems to be certain, for in a former number of the same journal, a copy of which lies before us, there is a letter from the firm admitting that they undertake the treatment of patients but defending themselves from the charge that by doing so they are acting in antagonism to the medical profession. The practice of taking x ray photographs might, perhaps, be defended more easily than the treatment of patients by x ray or other electrical methods but we must confess to some astonishment at finding that either practice is followed by a firm of good standing We are aware that electrical methods of treatment have unfortunately been taken up more or less by unqualified persons but we should hardly have thought it a politic procedure on the part of the firm in question We are not surprised to find that protests are being made against such an unjustifiable encroachment upon work which should be confined to medical practitioners

ROYAL COLLEGE OF SURGEONS OF ENGLAND HUNTERIAN FESTIVAL

IN February the anniversary of the birth of John Hunter is celebrated each year at the Royal College of Surgeons of England by the delivery of a Hunterian Oration This year the oration was delivered by the President of the College, Mr John Tweedy It will be found in full in another column and is commented on in a leading article The oration was followed this year by the Hunterian dinner, which is held biennially, the President being in the chair, supported by the Vice Presidents, Mr A W Mayo Robson and Mr Henry T Butlin About 100 guests were present, including distinguished representatives of various professions and callings, as will be seen from the following names the Duke of Abercorn, the Lord Bishop of Oxford, the Dean of Norwich, the Right Hon James Bryce, M P , the Hon Mr Justice Buckley, the Hon Mr Justice A T Lawrence, Sir John R Paget, K C , General Lord Cheylesmore (Mayor of the City of Westminster), the Vice-Chancellors of the Universities of Cambridge and London, the Dean of the Medical Faculty of the University of London, Sir William Ramsay, F R S , the President of the General Medical Council, the President of the British Medical Association, Sir Frederick Bridge, Mus D , Dr W H Cummings, Mus D , the Headmaster of Westminster School, Sir Harry H Johnston, Dr Edward A Wilson (surgeon of the National Antarctic Expedition), Sir William S Church (President of the Royal College of Physicians of London), Sir William H Broadbent, Sir Lauder Brunton, Sir Dyce Duckworth, Professor T Clifford Allbutt, Sir Frederick Treves, the Director-General of the Medical Department of the Royal Navy, the Director General of the Army Medical Service, and the Masters of the Merchant Taylors', Salters', Ironmongers', Clothworkers', Skinners', Leathersellers', Apothecaries', and Grocers' Companies By a curious coincidence the present Master of the last named Company is Mr H Percivall Pott, a descendant of the well known surgeon, Percivall Pott, who was one of Hunter's teachers and whose name is still well known in connexion with Pott's fracture The toast of 'The King" was proposed by the President who referred to the great interest taken in the medical profession by the King, as shown by the fact that he was an Honorary Fellow of the Royal College of Surgeons of England and also an Honorary Fellow of the Royal College of Physicians of London He had too shown his interest, perhaps even in a more important way, by his efforts on behalf of the hospitals of London and by his establishment of King Edward's Hospital Fund which was bringing a spirit of intelligent inquiry to bear upon the hospital administration of London and would, it might be hoped, result in the establishment of a rational system of management and expenditure In proposing the toast of "Queen Alexandra, the Prince and Princess of Wales, and the other Members of the Royal Family," the President remarked that the Queen was a meet helpmate for His Majesty in all good works and that the Prince of Wales showed his interest in hospital affairs by his presidency of King Edward's Hospital Fund He also alluded to the position held by His Royal Highness as President of the Cancer Research Fund and referred to his recent speech as showing a remarkable grasp of details connected with the problems with which that Fund had to deal The toast of "The Memory of John Hunter" was then drunk in silence Mr Mayo Robson proposed the toast of "The Visitors ' and in coupling with it the names of the Duke of Abercorn and Vice Admiral W H Henderson alluded to the good service that was rendered by the committee established under the auspices of the Duke of Abercorn to our sick and wounded officers The Duke of Abercorn, in reply, said he was glad of the opportunity—the first that he had had—of returning his cordial thanks to those members of the medical profession who voluntarily and generously gave their skill and their knowledge to help the wounded officers whom it was the object of the fund which he had started to benefit Vice Admiral Henderson also responded The toast of "The President and Orator ' was proposed by Sir William Ramsay who spoke of the President as "a man of few words but his words contained wisdom " A short reply by the President brought the proceedings to a close A programme of music was performed during dinner by the band of H M Coldstream Guards

FRENCH COPYRIGHT IN PROFESSIONAL PHOTOGRAPHS

ON Feb 10th judgment was delivered in a French law court in the matter of Dr Doyen *versus* a firm of photographers The facts of the case were these In June, 1898, Dr Doyen conceived the idea of having certain surgical operations "cinematographed" during their performance Six different operations were photographed jointly by two photographers, M Clément Maurice and M Parnaland The latter, it is alleged, sold prints from these films to the Société des Phonographes et des Cinématographes and the photographs were publicly sold and even exhibited by showmen (*par des forains*) in public places with Dr Doyen's name in large letters on the posters The following were the chief terms of the judgment delivered by the court The court condemned M Parnaland and the Société des Phonographes et des Cinématographes jointly to pay to Dr Doyen the sum of 8000 francs as damages on account of the charges The court ordered in addition that its judgment should be published in 15 journals to be chosen by Dr Doyen provided that the price of each insertion should not exceed the sum of 200 francs The court also ordered the confiscation and the surrender to the plaintiff of the subjects of the action This decision is of great importance as it lays down definitely the right of men of science to have absolute control over photographs and other graphic documents which may have been taken in their laboratories The decision is an altogether new one Our thanks are due to Dr Doyen for having provided our Paris correspondent with a copy of the judgment from which we have taken the above facts

HEMIPLEGIA WITH PARALYSIS OF THE THIRD NERVE ON THE OPPOSITE SIDE DUE TO TUMOUR OF THE TEMPORAL LOBE.

HEMIPLEGIA with paralysis of the third nerve on the opposite side usually indicates a lesion of the crus cerebri implicating the motor tract going to the opposite side and the third nerve on the same side The fact that this rule is not invariable is shown by the following case reported to the Société Médicale des Hôpitaux of Paris at the meeting of Jan 13th by M Menetrier and M Bloch A woman, aged 40 years, was admitted to hospital with recurrence of cancer of the left breast The primary growth was removed a year previously She was in a somnolent condition and answered repeated questions only , the monosyllables "yes" and "no." There was right hemiplegia with flaccidity of the muscles and without increase of reflexes. Babinski's sign was well marked. The upper part of the face was but slightly involved in the hemiplegia. There was complete paralysis of the left third nerve—ptosis, external strabismus, mydriasis, and protrusion of the globe. Neither vomiting nor headache was present. The patient became comatose and died. The necropsy showed that the cerebral peduncles were free from any secondary growth. But in the infero-internal part of the left temporal lobe was a tumour of the size of a small apple. It caused the base of the hemisphere to project for several square centimetres, pressed outwards the inferior temporal convolutions, and appeared on the surface between the optic chiasma in front and the cerebral peduncle behind. From the anterior part was a prolongation which compressed the third nerve at the point where it entered the wall of the cavernous sinus. A vertical section through the middle of the tumour and the whole of the cerebral hemisphere showed that the former crossed the fissure of Rolando and extended a considerable distance forwards. It was whitish, firm, of a diameter of four centimetres, and dotted with hæmorrhages. It was in contact with the internal capsule which it compressed. The cerebral peduncle was behind it and quite intact. Thus the crossed paralysis was due to two topographically distinct lesions; the tumour sent forwards an extra-cerebral prolongation from its inferior surface which crushed the third nerve while its upper and intra-cerebral part compressed the internal capsule. In contrast with this case M. Menetrier and M. Bloch referred to another case of cerebral growth secondary to cancer of the breast in which there was crossed paralysis of the third nerve due to a lesion in the usual position. The patient was a woman, aged 56 years, who was operated on for cancer of the left breast. 12 days later she was seized with right hemiplegia with complete paralysis of the left third nerve. The necropsy showed a nodule of cancer in the base of the skull compressing the left cerebral peduncle and left third nerve.

THE FATAL CASE OF PLAGUE IN THE MERSEY.

The s.s. *Crewe Hall* arrived in the Mersey on Jan. 30th from Rangoon. She was cleared by the Customs officers on the evening of the same day, the captain answering the usual questions and reporting "all well" on board. The ship was rummaged in the river on the following day, the water being too low (14 feet) to allow the vessel to dock. On the morning of Feb. 1st one of the Customs' officers noticed a lascar sick in his bunk, apparently dying. Upon inquiry he was informed that the man had had a severe cold for the previous seven days. He at once notified the port sanitary authority by special messenger and by telephone. This was the first notification which the authority received. Dr. W. Hanna, the assistant medical officer, visited the ship at once and interviewed the captain and the chief steward, the latter having attended and treated the lascar for the previous seven days. They stated that he had had high fever and they thought that he was suffering from malaria; they also mentioned that he had a painful swelling in the groin. The native serang also stated that the man complained of fever and a painful lump in the groin. Dr. Hanna found the man laid out and examined the body in the native sailors' forecastle; all that could be discovered on examination was a large bubo in the left femoral region. On reporting the matter to the port medical officer (Dr. E. W. Hope) the conclusion was arrived at that there was a suspicion of plague in the case and that it would be advisable to treat it as such. Accordingly, the native crew was cleared out of the forecastle, the body was removed, and the bunks and all effects of the native crew were disinfected. The "contacts," 15 in number, after bathing and putting on disinfected clothing, were removed to the port sanitary hospital for isolation. The rat-catchers to the authority were at once notified and visited the vessel but found no dead or sick rats. They set their traps at once and as a result only 11 rats were caught; these were forwarded to Professor R. W. Boyce, the corporation bacteriologist. A further disinfection of all suspected quarters of the ship was undertaken on Feb. 2nd; these have now been repainted. The cargo was discharged under strict supervision and a careful watch was kept for dead rats. Fumigation of the holds to destroy rats was carried out before the vessel sailed. On Feb. 2nd a post-mortem examination of the body of the lascar was made by Dr. Hanna and Dr. A. A. Mussen. There was marked discolouration of the skin over the bubo. The latter was found to be of large size, very hæmorrhagic on section, with much peri-glandular inflammation. There was also evidence of a septicæmic condition with a considerable amount of pneumonia. Material for bacteriological and microscopical examination was taken which was reported on by Dr. Hanna and later confirmed by Professor Boyce and Dr. E. Klein. Microscopically the gland juice showed very numerous plague-like bacilli. On culture (24 hours) a growth typical of the plague bacillus appeared and the organisms as regards appearances and staining reactions answered all the characters of that bacillus. The source of infection in the case of this lascar has up to the present time not been traced but the medical authorities consider the chances of further infection to be very remote.

FLIES AS DISSEMINATORS OF TUBERCULOSIS.

In 1887 Spillman and Haushalter found tubercle bacilli in the intestinal contents and in the excreta of flies in a hospital ward and Hofmann found the bacilli in flies fed on tuberculous sputum. In the *Boston Medical and Surgical Journal* of Dec. 15th, 1904, Dr. F. T. Lord has published some interesting experiments performed in order to ascertain the part played by flies in disseminating tuberculosis. 30 flies were confined in a glass jar and fed on tuberculous sputum. Within three days 26 died and the remainder had become very inactive. Six flies similarly confined and fed on non-tuberculous sputum died within two days, while four out of six flies fed on water, sugar, and meat were alive at the end of a week. Evidently the short duration of the life of the flies fed on tuberculous sputum was not due to the tubercle bacillus but to some other constituent of the sputum In sections of these flies tubercle bacilli were found in the intestinal contents but in no other part. Examination of cover glasses placed in the glass jar showed that the bacilli appeared in the excreta within 18 hours and that they had increased in number from an average of ten in a microscopic field of the sputum to 150 in one of the excreta. Each fly-mark contained an average of from 3000 to 5000 bacilli and about 2000 marks had been deposited by the 30 flies in three days, making a total of from 6,000,000 to 10,000,000 bacilli. These bacilli were much larger than those in the sputum and showed some evidence of branching. The jar containing the fly-marks was placed in a room and protected from strong diffused daylight by a board. Guinea-pigs were inoculated in succession with 100 fly-marks which were scraped off at intervals of one, eight, 15, 28, and 55 days. The first inoculation was subcutaneous and the others were intraperitoneal. The animals were killed after from five to seven weeks. Tuberculosis was produced in the first three animals inoculated, showing that virulent bacilli were present in the excreta for at least 15 days. After this time the results were negative. The animal inoculated with the marks which were only a day old showed generalised tuberculosis. In the others the process was less extensive. Dr. Lord concludes that fly-marks contaminated by tubercle bacilli may be a source of tuberculosis in man for at least 15 days after their deposit if exposed only to diffuse daylight. One way in which the bacilli might be transferred to man is by the contamination of food with the excreta. To determine whether there was any danger of infection by inhalation Dr. Lord exposed guinea-pigs to a gentle current of air drawn through a glass cylinder in which 23 flies were confined with tuberculous sputum and on which they deposited a large number of marks. The animal was killed and showed no trace of tuberculosis. On the other hand, Cornet has shown that guinea-pigs are readily infected when exposed to tuberculous dust. Evidently fly-marks are not a source of danger when merely exposed to a gentle current of air. Dr. Lord observed that flies readily feed on tuberculous sputum even when other food is accessible. If they afterwards alight on human food they may deposit tubercle bacilli in great numbers. It follows that flies should not be allowed access to the sputum of consumptive patients.

"KINDS OF INSANITY."

THE preparation of a new set of statistical tables by the Medico-Psychological Association of Great Britain and Ireland for the annual recording of the vast clinical and pathological data and returns of all public asylums in the future has brought forward the inevitable question of the nomenclature and classification of the insanities. Dr. C. A. Mercier, in an article in the *Journal of Mental Science* for January, deals with the "kinds of insanity" which he thinks fulfil the necessary conditions of true diseases. The arrangement suggested is first to separate congenital from non-congenital cases of insanity. The congenital cases would include all idiots and most imbeciles. The classification of these is a matter of subordinate importance, whereas the division of the insanities proper into natural groups is the main desideratum in mental science and the most important aid to clearness of thought, of diagnosis, and of prognosis. Cases of insanity are proposed to be considered as of two classes—viz., general paralysis (paralytic dementia) and non-paralytic insanity. Dr. Mercier suggests that the latter class contains "diseases sufficiently distinct to merit the same separation that is given to general paralysis. ... .. As to general paralysis the symptoms are so distinct that it is recognisable at every stage in its progress. It has a definite history, runs a definite course, and forms a complete clinical picture separable from that of any other case of insanity." Examining other varieties of insanity and their titles or claims to be called diseases, Dr. Mercier would admit "acute delirious mania" owing to its characteristic symptoms and its course as a definite variety of insanity. "The clinical picture of acute delirious mania is distinct and prevents it from being confused with any other cases of insanity. On the contrary," he says, "puerperal insanity presents us with no distinct clinical picture. The very fact that it has been divided into puerperal mania and puerperal melancholia is proof of what I say. Puerperal insanity is acute insanity occurring within an uncertain time of childbirth, and if the antecedent of childbirth is disregarded there is nothing whatever in the clinical picture of the disease that is different from other cases of acute insanity that have no connexion with the puerperium, or even from acute insanity occurring in men." The insanity of pregnancy is regarded as having a much better right to be considered a disease, "for the fact of pregnancy is a continuing feature in the clinical picture, a feature which at once marks off the case from all other cases of insanity." What is true of the insanity of pregnancy, he adds, is emphatically true of the insanity of lactation. It is an insanity of exhaustion—of innutrition—and differs in no respect from other cases of insanity of similar origin. Few cases of insanity occurring at the menopause in women deserve recognition as a separate variety of insanity. Similar cases may occur at other times of life and present the same clinical picture. The definite form of insanity of the menopause "with its special facies" is, says Dr. Mercier, rare. Senile insanity has no right to a special place in nosology. "The term means, it appears, insanity not assigned to any distinct category except by its occurrence in advanced age. It would, in my opinion, be unreasonable to base the differentia of the disease on so slender a foundation." The insanity of epilepsy is admitted to have "a good title to the denomination of a disease." Cases of insanity associated with bodily diseases, whether the latter be regarded as a cause or not, in no case present a clinical picture of sufficient distinctness to entitle them to separate rank as diseases. Dr. Mercier would admit the claims of stupor, paranoia, recurrent and alternating insanity, and the two forms of insanity occurring in adolescents or young adults known as hebephrenia and katatonia. Cases of fixed delusion would also find a place in classification, being further subdivided as the delusions are persecutory, exalted, and personal. Alcoholic insanity would be recognised in its subdivisions of *mania a potu*, delirium tremens (acute forms), or alcoholic insanity proper of the chronic form. This threefold subdivision of alcoholic insanity would exclude all cases in which alcohol was not the main actuating cause of the malady. The above-named varieties of insanity, concludes Dr. Mercier, "have claim to the title of distinct diseases from the distinct clinical pictures they present; all other cases must be lumped together under the heading of insanity *simpliciter*."

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

AT the next meeting of the above society to be held on *Tuesday, Feb. 28th, at 8.30 P.M., Sir Frederick Treves* will open a discussion on the Subsequent Course and Later History of Cases of Appendicitis after Operation. Sir William Broadbent will speak next in order and other eminent physicians and surgeons have promised to take part in the discussion. Special attention will be directed to the following subjects: 1. The frequency with which complications such as the following occur during convalescence: femoral thrombosis, pulmonary embolism, pylephlebitis and suppuration of the liver, empyema and septic broncho-pneumonia, acute intestinal obstruction, residual abscesses, pyosalpinx and suppurating ovaries, and fæcal fistula. 2. The after-results in cases where the appendix has not been removed. 3. What proportion of cases are there in which the symptoms are not relieved by operation or in which recovery is imperfect? Statistical tables have been promised from several hospitals giving information on these points. In view of the many questions to be considered the debate will doubtless be adjourned. It is important that those gentlemen who wish to speak should communicate as soon as possible with the honorary secretaries, 20, Hanover-square, London, W.

THE SARANAC LABORATORY FOR THE STUDY OF TUBERCULOSIS.

WE have received a copy of a publication with the title, "Studies from the Saranac Laboratory for the Study of Tuberculosis, E. L. Trudeau, M.D., Director, 1900–1904." It is published at the office of the *Journal of Medical Research*, 688, Boylston-street, Boston, Massachusetts, U.S.A. It contains several interesting communications, notably the records of a series of observations on the tuberculin reaction by Dr. E. L. Trudeau, Dr. E. R. Baldwin, and Dr. H. M. Kinghorn. The first subject of inquiry was, Can the diagnostic use of tuberculin scatter the disease and produce new tuberculous foci? This is an important point, as tuberculin is employed for diagnostic purposes not only in relation to cattle but also in actual medical practice. The detection of a partial reaction enables the necessary treatment to be carried out at a stage of the disease in which the prospects of treatment are very favourable. In localised corneal tuberculosis of the rabbit's eye no spread of the disease in the cornea could be observed after the use of tuberculin injections. On the contrary, a favourable absorptive influence was noted upon the diseased focus. From other investigations it was concluded the specific tubercles must be present in order that a local tuberculin reaction could be manifested. It was, however, demonstrated that local reactions with rise of temperature occasionally resulted from the injection of trypsin, peptone, and sodium cinnamate. These reactions were not uniform and only took place when large doses were injected. Except in fatal poisoning by peptone the reactions did not bear a close resemblance to the typical tuberculin reaction. It is possible that the mixture of albumoses, known as peptone, contains proteid substances chemically similar to tuberculin, the injection of which excites a more or less marked reaction in the tuberculous tissue according to "the age and sensitiveness of the tubercles." Some valuable work is evidently being accomplished in the Saranac laboratory and doubtless further results will in due time be published.

THE DANGERS OF FLANNELETTE.

OUR Manchester correspondent writes: You and your readers may perhaps be weary of the subject of flannelette, but the death-roll, the result of its use, is so heavy as to excuse the mention of two cases that have just occurred here. One child, four years old, was left alone for a few minutes when her clothes caught fire and she was fatally burnt. The other case was very similar. The child was dressed in flannelette, left for five minutes, and when the mother returned was found enveloped in flames which she could not extinguish. The city coroner has often spoken of the danger of this material and has consequently been accused of trying "to rob the poor of their cheap and warm covering." The non-inflammable variety is said to be obtainable at $2\frac{1}{2}$*d.* per yard. There is, moreover, another safeguard the use of which has been strongly urged by the coroners of Warrington and Lancaster. The latter said that the investment of 1*s.* 6*d.* in a fireguard was better than an investment with the undertaker after a child had died a terrible death. And the former said just before Christmas that he had held 14 inquests this winter on children who had been burned, fireguards having been absent in every case. From this gentleman's statement it would seem that callousness and indifference are not confined to the social stratum in which these occurrences usually take place. He said "it was no use making representations to the county council when they sneered at them and the chairman said it would be grandmotherly legislation to adopt their suggestions." These tragedies, he said, "occurred among a class of people who brought children into the world and were absolutely indifferent to their education, physical culture, and welfare, and upon whom no moral suasion had any effect. The legislature should compel them to do what they ought to do." This is a severe accusation to make but though, happily, there are exceptions, those who know most about the matter must acknowledge its truth.

THE JENNER SOCIETY.

HARDLY any fact in epidemiology is better attested than the efficacy of recent vaccination in conferring immunity from small-pox and as it is well known that the protection gradually wears off in the course of years revaccination at proper intervals is essential for safety. In its report of the period from July 1st, 1903, to Dec. 31st, 1904, the executive committee of the Jenner Society expresses regret that the Government has not seen its way to give facilities for introducing a Revaccination Bill and in a subsequent paragraph the report alludes to the influences by which Members of Parliament are likely to be deterred from supporting such a measure. The working classes, with whom the voting power of the constituencies resides, do not recognise the advantages of vaccination and are sometimes actively hostile to the practice. "For such a state of things there is only one remedy, and that is education." The society acts up to its own precepts by liberal distribution of leaflets, pamphlets, and other forms of literature in favour of vaccination, specimens of which may be obtained from the honorary secretary of the society, Dr. Francis T. Bond of Gloucester. In some of these the arguments are strengthened by well-executed photographs showing the marked contrast between modified and unmodified small-pox. Some administrative defects connected with the existing system of vaccination are commented on and the report, which is signed by the Dean of Gloucester, closes with the remark that much remains to be done which the society is unable to attempt for want of funds.

THE MAGNET IN OPHTHALMIC SURGERY.

IN three important articles contributed to our contemporary the *Ophthalmoscope* Professor J. Hirschberg of Berlin, Professor O. Haab of Zürich, and Mr. S. Snell of University College, Sheffield, give the results of their experience in treating cases of accident where fragments of iron have penetrated the eye and are lodged in its tissues. Statistics of a valuable nature can, of course, only be obtained by those who are practising in large cities, or at least in towns where there are numerous trades engaged in, or associated with, metallurgical processes and in the varied occupations where filing, rivetting, hammering, and the manufacture of tools engage the attention of workmen. Professor Hirschberg informs us that there are 50,000 iron-workers in Berlin and that in the course of the last 25 years he has performed 307 operations with the magnet. Professor Haab has had more than 200 cases during the last 12 years under his care and Mr. Snell has had fully 300 instances in which the electro-magnet has been employed. It is justifiable to draw some general conclusions in regard to the utility of the magnet in ophthalmic surgery from 800 cases. In the first place, the general statement may be made that fragments of iron or steel should never be allowed to remain imbedded in the tissues of the eye. Even though they appear to excite no inflammation and are not productive of pain, slow changes are set up which ultimately lead to the impairment of vision. Professor Hirschberg records one remarkable case in which a splinter of iron penetrated the eye and lodged in the retina of a man with preservation of almost normal vision, yet on having the opportunity of again examining the patient after 26 years Professor Hirschberg found that he had become blind from cataract and cyclitis a year after the accident. In the next place, the presence and position of the fragment should be carefully ascertained by naked-eye inspection, by oblique illumination, by the ophthalmoscope, or by means of the sideroscope, or by radiography; its location being determined by one or other of these means so far as possible with precision, the form of magnet to be used and the mode in which it should be applied with the least harm to the patient and the best prospect of success in removing the splinter, should be taken into consideration. Where the fragment is small and superficially situated, as in the anterior chamber or imbedded in the iris, it may sometimes be extracted through the corneal wound with a hand magnet, but if it be deeply situated or firmly fixed a stronger instrument is commonly required and then one or other of the giant magnets devised by the authorities above mentioned should be employed It must not, however, be supposed that this is an easy matter or one to be undertaken in an off hand manner By Professor Haab, who first devised the giant magnet, it is pointed out that inasmuch as the pull upon the splinter on the application of the instrument is apt to give pain and to cause the fragment to be pressed violently into the ciliary region, whence it is not easy to disengage it, the patient should not be placed on a couch with the head fixed but that he should sit upright and thus be able to withdraw his head when pain is felt Professor Haab thinks that the electric current should by a movement of the foot be switched on or off in order that the splinter may be moved by a series of jerks At the same time the overheating of the pole introduced into the eye should be avoided He holds, moreover, that the intruding substance on making its way out, if it be deeply implanted in the vitreous, does not follow the way of entrance but the lines of power of the magnetic force Hence it slides almost regularly around the lens and appears behind the iris and when it has gained this position the patient should be so placed that the point or pole of the magnet is opposite the middle of the cornea As Mr W Lang suggests a steel spud may then be introduced into the anterior chamber, the base of the spatula being connected with Haab's magnet by means of a few strands of soft iron wire, and the particle clinging to it is then readily removed through the corneal opening Iridectomy should be rarely performed Mr Snell, who first suggested the employment of an electro magnet in ophthalmic surgery so long ago as 1881, has by one or two slight modifications of his original instrument designed an extremely useful and handy form of magnet well adapted for all ordinary emergencies It is now in common use in this country When attached to a quart bichromate battery it is capable of raising and of holding suspended a weight of at least seven ounces He contends that the smaller instrument which he employs possesses distinct advantages over the giant magnet It is more easily handled, more portable, and far less expensive Where failure to remove the foreign body occurs on the first attempt, Professor Haab states that he has been successful after two or three trials It is to be noticed that a large proportion of these accidents perhaps half, are followed by cataract Mr Snell gives some interesting statistics showing that in by far the larger number of cases the splinter is lodged in the vitreous, the size varying from small particles to fragments weighing 36 32 and 22 grains

---

THE medical officer of health of the Cape Colony states that for the week ending Jan 21st the condition of the colony as regards plague was as follows No case of plague in human beings was discovered during the week but plague infected rodents were found at Port Elizabeth and East London, together with 2 plague infected cats at the latter place In other districts no case of plague in either man or other animal was discovered

---

A DISCUSSION will be opened on Saturday, March 4th, in the Council Chamber, Town Hall, Newcastle upon Tyne, on the Aerial Dissemination of Small pox round Hospitals, by Dr Henry E Armstrong The chair will be taken at 11 A M by Mr W Whitaker F R S , F G S , chairman of the council of the Royal Sanitary Institute, under the auspices of which the discussion has been arranged

---

A MEETING of the Hospitals Association will be held on Friday, March 3rd, in the hall of Charing Cross Hospital, at 8 P M Mr Thomas Bryant will occupy the chair A paper will be read by Dr Donald J Mackintosh, medical superintendent of the Glasgow Western Infirmary, *on the* Control of Hospital Expenditure with Efficiency

---

THE annual meeting of the After Care Association, which exists to look after the interests of poor persons discharged recovered from asylums for the insane, will be held at 52 Wimpole street, London, W , by kind permission of Dr and Mrs Harrington Sainsbury, on Wednesday next, Feb 22nd, at 2 45 P M *The Bishop of St Albans will preside*

AT the Harveian Society of London, Stafford Rooms, Titchborne street, Edgware road, W , on March 9th, at 8 30 P M , Mr Malcolm A Morris will deliver the Harveian lecture on Some Modern Therapeutic Methods in Dermatology, with exhibition of cases treated by the x and the Finsen rays

---

THE dinner in honour of the celebration of the hundredth anniversary of the birth of Señor Manuel Garcia will take place on March 17th, at 7 30 P M , at the Hotel Cecil

---

SIR Michael Foster has decided to offer himself for re election to the next Parliament as Member for the University of London He seeks re election as a representative of science and higher education, if re elected he will take his seat as a member of the Liberal party A committee, with Sir Thomas Barlow as chairman, has been formed to promote his election This committee comprises graduates belonging to different political parties who are supporting Sir Michael Foster on the ground of his many public services and in the belief that his special knowledge will continue to prove of great value to the House of Commons

---

THE epidemic of typhoid fever at Lincoln is assuming serious proportions Over 500 cases have been reported, with 30 deaths

MEDICINE, ITS PRACTICE AND ITS PUBLIC RELATIONS

CHAPTER I

Preliminary Editorial Note

WE propose in a series of articles under the title of Medicine, its Practice and its Public Relations, to present to our readers a picture of the present position of the medical profession considered especially with regard to the existing conditions of society at large in this country The articles have been written by a member of our staff and must not be regarded as the last editorial word upon questions some of which are complex and many of which are vexed That we are prepared to issue the series must be accepted as a proof that we consider the writer well equipped for his task as well as in the main sound in his conclusions, while the greater part of his facts will be found scattered through our columns The bringing together of these facts in a systematic way and their presentation as a whole with due regard to their individual importance cannot fail to be valuable to our readers, for such a *résumé* will serve both as a report upon matters of common knowledge and opinion which will save much wearisome work of reference, and, at the same time, as material for debate where subjects of dispute are touched upon The utility of debate depends largely, almost wholly, upon a clear understanding of what are the points to be debated and in the critical period of our social history that is now with us it is of the *first importance* that medical men should know exactly what it is that makes the times out of joint before discussing the proper remedies for the reduction of the dislocations. There is no doubt that the profession of medicine has of recent years made vast strides forward scientifically, yet medical education was never more subjected to adverse criticism. In many respects the life of the medical man of the present day, in whatsoever sphere he is called upon to exercise his calling, is a more dignified one than it was half a century ago, yet never were the hardships and injustices of our career more obvious or more roundly resented. The chapters which will follow deal with the professional life of the British medical man in all its different phases and are intended to summarise and to appreciate at their proper worth the various grievances which undoubtedly prevail. We are certain that those of our readers who have the interests of the medical profession at heart will find such a work valuable. Where they agree with the writer their opinions will be reinforced; where they disagree they can decide, after any discussion which may seem necessary, either to maintain or to qualify their views. In either case they will be compelled to think what those views really are and upon what logical grounds they are founded, a form of contemplative attention which the social side of the medical career seldom receives.

Nothing has of late been more marked in the vital scheme of this country than the destruction of tradition. The spirit which was once wont to estimate as an act of impiety any effort to improve upon the methods of our grandfathers is well-nigh extinct among all classes, however varied their intellectual equipment, their religions, or their position; and, as a matter of course, the profession of medicine has shared in the general striving for improvement. A striving for improvement is, however, apt in the first instance to lead to muddle and discord. Reforms are advocated for which the world is not ready, extreme remedies are recommended for conditions that are not so parlous as they appear. The policies of reformers become to some extent discredited, as their efforts, however well-directed, are largely nullified by the obvious impracticability of some of their proposals. It is necessary, if the medical profession is to formulate for its guidance and improvement any general scheme of reform, not only that the grievances complained of should be verified as actually existing but that the possibility of their removal should also be demonstrated. The series of articles will discuss the grievances of the medical profession as a whole, those of consulting physicians and surgeons, those of general practitioners, and those of the staffs of the naval, military, colonial, and civil services. The conditions of employment, the average rates of emolument, the meanings of these rates when compared with the earnings of other professions, will have to be considered and in this way it will be possible to ascertain the following: (1) what things are certainly hardships which it is the duty of every one of us to strive to remove; (2) what things are expressions of faults in our general social scheme, where the duty of finding a remedy can hardly be said to devolve on the medical profession alone but rather belongs to the whole body politic; and (3) what things cannot be said to be general professional grievances at all, although in individual instances members of the medical profession may be oppressed by them. It is usual for us to receive weekly, and during the sessions of the General Medical Council it is invariable for us to receive daily, communications from readers calling attention to the inactivity or lack of sympathy of the controlling body of the medical profession. Almost without exception these communications are sent to us by persons who have not in their minds a clear conception of what the duties of the General Medical Council are. They do not realise either the vast scope of the work of that body in some directions or its limitations in others, and as a rule they regard the Council as a body existing for the support and protection of the medical profession rather than as a body whose duty lies wholly towards the public, inasmuch as the reason of its existence is simply to guarantee that the public is served by a properly equipped, properly educated, and properly behaved body of medical men. The series therefore fitly commences with a brief statement of the duties and scope of the General Medical Council, passing on to the general and the special grievances of the medical profession. The overwork in some branches of our profession and the underpay in others are noticed, as is the inequality of the distribution of our medical service whereby vast districts—vast, that is, in comparison with the size of these islands—are left without medical service, while other communities have such a choice of professional assistance offered to them that all the evils of overcompetition spring up and menace the amenities of professional life. It will be necessary in such cases to consider the remedies and it cannot be too definitely and certainly stated that the more altruistic the programme of reform is which may be adopted by the medical profession the more practical it will be. All over the civilised world the life of the medical man is recognised as adorned by self-sacrifice. In all countries the medical man is expected to place his services at the disposal of the sick, sparing not time or talents or strength in his endeavours to relieve pain or to save life and giving no thought to reward. No other professional man is placed in the position towards his fellows that the medical man occupies, because those who need the services of a medical man have claims the elementary simplicity of which are recognisable by all. A man may want to go to law or to build a bridge, he may want to do either thing most urgently, but no one will call either the solicitor or the engineer inhuman if he is not prepared to give his professional services immediately and gratuitously where the applicant is without means. Yet not only unprotestingly but with alacrity the medical man does his best for the poor, the claims of pain and sickness being paramount over all personal considerations. It is natural, therefore, that the medical profession should expect that the public which it serves in so ungrudging a manner should be willing to see the calling of medicine placed upon a secure and dignified basis. But this expectation must be suppressed. No attention whatever will be paid by the public at large or by the legislative councils of the country to any such claim, and every scheme for the improvement of the medical profession must be honestly founded upon principles that would work to the advantage of the public. There should be no difficulty about the matter. It is clearly in the interests of the public to be served by capable men happy in the exercise of their talents and happy in the dignity of their calling, and medical men should ask only for the public recognition thus implied.

The training of the medical student is a matter of the first importance in a consideration of the state of the medical profession. In respect to medical education, the debates which have during the last two or three years taken place at the sessions of the General Medical Council show how increasing are the difficulties here. Medical science is advancing by geometrical progression, encroaching in every direction upon provinces which were wont to be considered as definitely allocated to other sciences. Similarly the public at large is vastly improved in general knowledge and requires of those who advise it, whether in theology, law, medicine, or what not, some recognition of this fact. The professional man can no longer out of his superior learning counsel his clients dogmatically or empirically; so that from the mere circumstance that the public is better mentally equipped it is necessary that the education of the medical man should be wider—that is to say, that for the medical man at the present day a larger general culture is required in addition to a more complicated and elaborate professional equipment. How, then, is time to be found for the student to learn even the bare irreducible minimum of what he must learn? or, to get a little further back, what constitutes the irreducible minimum for which time must be found during its acquisition? Here the question is at once obscured by the fact that in the United Kingdom many different examining bodies provide separate schemes of education for medical students, the coördinating authority being the General Medical Council, whose duty it is to see that the qualifying examinations of the various bodies are properly conducted and properly standardised. Nor is the multiplication of educational boards and systems the only difficulty. It is an unfortunate fact that the limits of the authority of the General Medical Council are ill defined, some of the qualifying bodies believing that the Council has not the powers which it claims, so that the extent to which a central control really exists, so far as medical education is concerned, is somewhat a matter of doubt. The General Medical Council can, and does, prevent the evils to the public at large which would result from a down-grade competition between the qualifying bodies, but that it possesses much more coördinating influence than is thus proven appears doubtful. A very considerable easing of the situation would be effected by the creation of a one-portal system whereby every medical man in the United Kingdom would enter the medical profession after the passing of one and the same set of tests. This one-portal system has been advocated at different times by THE LANCET and is again to be advocated in these articles. Times have changed since we in these pages urged the one-portal system as a remedy for most of the existing abuses. Had the system then been adopted we have no hesitation in saying that one of the most obvious grievances in the medical profession would never have sprung into being, for we should not see the London medical student placed in an apparently inferior position to the Scotch or Irish or provincial student of similar attainments. The fact remains, however, that the one-portal system did not commend itself sufficiently to the country at large to obtain legislative support and the chances of obtaining it now are, we fear, very small. But advocacy of its adoption will serve a good purpose—the matter should be threshed out if only to prevent the eternal shelving of questions of reform. If, after mature consideration and debate, the idea of securing a one-portal system in this country appears completely ideal it will save time that we should frankly admit the fact, when abuses that are supposed to be waiting alleviation until the good time when the one-portal system comes into being will be tackled from other aspects. On these matters our endorsement of the writer's views can only be regarded as general, our hope in publishing them being to elicit some solidarity of opinion among medical men upon the matter. It is, in fact, this solidarity of opinion, this real union of medical men, that we want to see created. We want those medical men who take pride in their calling to think for themselves what the present sociology of medicine is, to note where the calling of medicine is out of touch with the times and the general polity of this country, and to appreciate what are its undeniable disabilities and how far they can be practically remedied, not only without trenching upon the rights of the public at large but actually with benefit to that public through the resulting supply of a finer quality of service.

ASYLUM REPORTS.

London County Epileptic Colony, Ewell (Report for the year ending March 31st, 1904).—The colony was formally opened under happy auspices on July 1st, 1903,[1] when on the occasion of the visit of H.R.H. Princess Louise, Duchess of Fife, and in the presence of the chairman of the London County Council and a large assembly of visitors, the opening ceremony was performed by the Duke of Fife. A handsome brass tablet has been placed in the entrance hall to mark the occasion. This therefore is the first report. The colony owes its origin to the fact that the asylums committee of the London County Council was impressed with the knowledge that among the *epileptics housed in its asylums there* were some 300 patients whose disease was mild in character and who seemed suitable to enjoy the benefits of colony or farm life. Accordingly an estate of 112 acres was purchased near Ewell, Epsom, on which a system of villas and buildings of a suitable character were erected. All the villas are of a one-storeyed character and provide accommodation each for 38 patients. The warming and ventilation are on the latest approved pattern and the buildings are lighted throughout by electricity. Roads have been made and gardens planted, the gardens of the villas being separated by earth banks or belts of planted trees and shrubs, so that ingress and egress are found only by the paths. The total number of patients admitted during the year was 315, comprising 250 males and 65 females. During the year the death-rate was low, there being only 17 deaths (14 males and three females). The medical superintendent, Dr. C. H. Bond, states in his report that private cases are admitted but that as the number of such cases received has been small "there still remains one villa not yet in occupation." The necessity of vigilance in regard to the class of patients is emphasised. Thus of the 315 cases sent to the colony 80, or [illegible] distributed as follows: 19 per cent. of cases of insane heredity, 17 per cent. of epileptic heredity, and 10 per cent. of alcoholic heredity. "A well-defined history of trauma, in the form of either injuries to the head or severe falls productive of shock, was found in as large a proportion as 14 per cent." Arterio-sclerosis was present in 14 per cent. of the admissions. Farm and garden work is systematically and daily taken part in by the patients, while the grounds are freely open for all to stroll about in during the intervals. "In a few instances the character of the men's labour is really that of skilled workmen, in about a third it is of fair value, but in the case of the majority it is crude and that of men entirely unaccustomed to agricultural pursuits." The patients are under regular medicinal treatment which includes bromide of strontium and a specially regulated diet. Cricket and other games are provided. The Commissioners in Lunacy state that the colony consists of able-bodied working epileptics, that the buildings are well constructed and suitable to their purpose, that the colonists were neatly clad and looked in good health, and that satisfactory progress has been made in the colony during the first year of its existence.

"LA MÉTAPSYCHIQUE."

ALTHOUGH opinions differ as to the soundness of the *hypotheses discussed* at the meetings of the Society for Psychical Research, there is no denying that the society has secured the active sympathy and coöperation of several eminent authorities in orthodox physical and biological science. At the annual general meeting held at 20, Hanover-square, London, W., on Feb. 6th, an address was delivered by the newly elected president, M. Charles Richet, professor of physiology in the Paris Faculty of Medicine. The proceedings commenced with some brief remarks by the retiring president, Mr. W. F. Barrett, F.R.S., professor of physics in the Royal College of Science of Ireland. Professor Barrett said that the acceptance of the chair by Professor Richet marked an epoch in the history of the society and was also a token of international amity. Professor Richet was a courageous defender of truths which "official science" still regarded with disdain and it was discreditable that science had shown such hostility, not only to the recognition but even to the investigation of supernatural phenomena. Professor Richet, who spoke in French for about an hour, delivered an address which was admirable from the rhetorical, apologetic, and argumentative point of view. Before proceeding very far he made a practical suggestion of obvious value—namely, that a hand-book dealing synthetically with the immense accumulation of recorded facts was a great desideratum. All branches of knowledge were defined and described in treatises which were useful, not only for reference but for the instruction of beginners, and occult science ought to be in possession of similar advantages. "Occult science" was, however, itself an unsatisfactory term, for all sciences at their outset were occult and remained more or less in that condition until they ultimately became exact. After reviewing the objections which attach to the terms "psychical science," "spiritistic science," and the risk of a partial confusion between the words psychical and psychological, he proposed the adoption of the newly-coined designation "la métapsychique." In the proposed text-book metapsychical phenomena would be classified according as they were either (1) purely psychic, involving no vibration or movement of matter; or (2) purely material. Premonitions and telepathy were examples of purely psychic phenomena, while raps, materialisations, passage of solid substances through other solid substances, and levitation were examples of material or mechanical phenomena. Questions relating to raps, luminous phenomena, spirit photography, and clairvoyance were next discussed at much length. In conclusion, Professor Richet said that while he had no doubt as to the reality of many of the phenomena he thought that no satisfactory explanation had as yet been suggested. An explanation would, however, be found some time or other, just as the planetary motions had been observed before they were explained by Kepler and electrical phenomena before they were explained by Ampère, Faraday, Clerk Maxwell, and Hertz. A vote of thanks to Professor Richet for his address was proposed by Sir Oliver Lodge, seconded by the Hon. Everett Fielding, and carried by acclamation in a crowded meeting.

---

[1] An account of the opening appeared in THE LANCET of July 11th, 1903, p. 110.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary meeting of the Council was held on Feb. 9th, Mr. JOHN TWEEDY, the President, being in the chair.

The death in his ninetieth year of Mr. Luther Holden was reported. He was past president and past member of the Council and of the Court of Examiners. He was also senior Fellow of the College. A resolution was passed expressing sympathy with Mrs. Holden and recording the Council's appreciation of his services to the College.

Diplomas of Membership were granted to 99 successful candidates and diplomas in dental surgery were issued to nine candidates found qualified in dental surgery.

It was also resolved to issue jointly with the Royal College of Physicians of London diplomas in public health to 17 successful candidates.

Mr. W. H. A. Jacobson was re-elected and Mr. Bilton Pollard was elected a member of the Court of Examiners. Mr. Thomas Bryant was reappointed to represent the College on the council of Queen's Victoria Jubilee Institute for Nurses for three years.

It was resolved—

> That a committee be appointed to consider and report upon the practicability of the institution by the College of a school for the teaching of the early and intermediate subjects of the medical curriculum and of advanced pathology.

A letter was read from Mrs. Silcock thanking the Council for the expression of its sympathy with her in the loss of her husband.

Dr. J. Ward Cousins was reappointed the representative of the College on the Central Midwives Board.

A letter was read from the President and the general secretary of the Fifteenth International Congress of Medicine to be held at Lisbon in April, 1906, asking the College to send a representative to the Congress and expressing the hope that they may be able to announce the adhesion of the College to the Congress in the next number of the official programme. It was resolved that a representative should be sent but the selection was postponed to a later date.

Obituary.

LUTHER HOLDEN, F.R.C.S. ENG.,

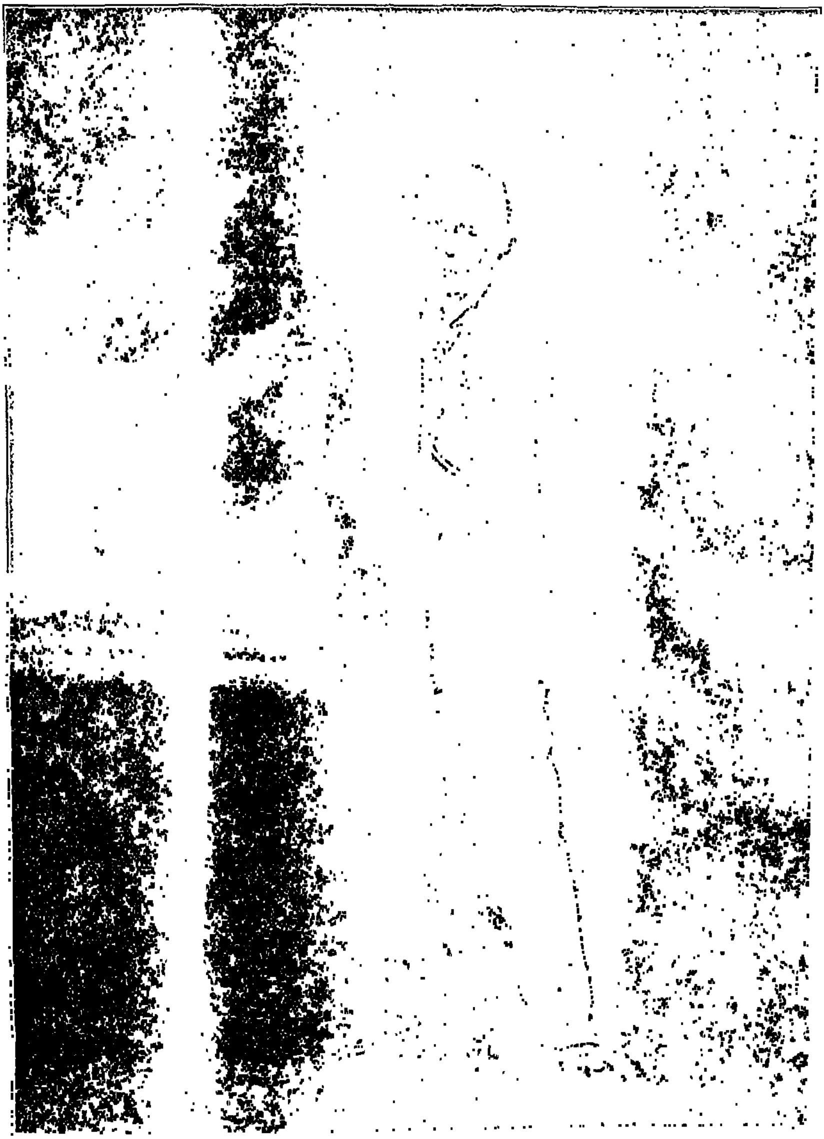
CONSULTING SURGEON, ST. BARTHOLOMEW'S HOSPITAL.

MANY generations of St. Bartholomew's men will have heard with regret of the death on Feb. 6th, in his ninetieth year, of Luther Holden, consulting surgeon to the hospital. He came of an old Staffordshire family, being the second son of the Rev. Henry Augustus Holden, and was born in Birmingham on Dec. 19th, 1815. His elder brother, the Rev. Henry Holden, D.D., honorary canon of Durham, is still alive and is in his ninety-first year, having been born on July 7th, 1814. Luther Holden's father was assistant curate at Wolstanton in Shropshire where, among other duties, he educated his son Luther, and it having been determined that Luther should follow the medical profession, he was, when about 17 years old, apprenticed to Stanley, then one of the surgeons at St. Bartholomew's Hospital. Besides studying in London Holden resided for a year in Berlin and for another year in Paris, reaping there the benefits of the French method of teaching anatomy, which was in those days far superior to that of other countries.

In 1838 Holden became a Member of the Royal College of Surgeons of England and was for some years engaged in teaching anatomy to students of St. Bartholomew's in the dissecting room, although he held no official position at the hospital. On Christmas Eve, 1844, he was elected a Fellow of the Royal College of Surgeons after the first examination held for this diploma. His first official connexion with the school of the hospital was in 1845 when, as appears by the issue of THE LANCET of Sept. 27th of that year (the "Student's Number"), he was appointed as superintendent of dissections, his colleague being Mr. McWhinnie. In 1859 we find him noted as lecturer upon descriptive and surgical anatomy, his colleague being Mr. Skey. In the year 1860 he attained the wish of his heart, being elected assistant surgeon, his age being then 45 years. There were then four surgeons—namely, Lawrence, Stanley, Lloyd, and Skey, the assistant surgeons being Wormald, Paget, McWhinnie, and Coote. Holden became assistant surgeon to Skey. Between 1860 and 1865 all the four senior surgeons retired and Holden became full surgeon in 1865, taking for his assistant Alfred Willett, now a consulting surgeon to the hospital. Holden served for 15 years as surgeon, retiring under the age limit in 1881. He never cared about private practice and consequently did but little.

Holden's work in anatomy was chiefly limited to educational work but in 1850 he read a paper before the Abernethian Society of St. Bartholomew's Hospital on the mechanism of the hip-joint which referred to the influence of the pressure of the atmosphere in retaining the head of the femur within the acetabulum and also to the important part which the anterior portion of the capsular ligament played with regard to the erect attitude of the body. In 1851 there appeared his "Manual of the Dissection of the Human Body."

In 1855 was published the book by which Holden was known to nearly every medical student in the kingdom—viz., his "Human Osteology." It was magnificently illustrated by Holden himself and was the first book in which the now universally used system was employed of marking the origin and insertion of the muscles by means of red and blue lines. When it appeared the reviews generally contained the remark "Why did no one think of this before?" and it may be said that practically every work on osteology which has appeared since has followed the same plan for indicating muscular attachments. Moreover, the late Sir William Flower, when Conservator of the Royal College of Surgeons of England, adopted it for the marking of mounted specimens. Another admirable work by Holden was his "Landmarks, Medical and Surgical," which made its first appearance in 1866 as an article in the St. Bartholomew's Hospital Reports for that year. A further portion of the work appeared in the reports for 1870 and in 1876 it was published as a separate book. As may be gathered from the title it taught the student how



LUTHER HOLDEN, F.R.C.S.

[illegible] he could learn on the [illegible] was yet unbroken. [illegible] is very much to the [illegible] is. He was elected [illegible] two colleagues being John Simon and George Murray Humphry. In 1873 he was elected a member of the Court of Examiners, together with John Marshall and Timothy Holmes, and in 1875 he was elected a member of the Board of Examiners in Anatomy and Physiology, among his colleagues being William Scovell Savory, John Birkett, John Wood, Henry Power, and Christopher Heath. In 1879 he was elected President of the College, having been a Vice-President for the two previous years. In 1881 he delivered the Hunterian oration. In this discourse, owing to careful research into the history of Hunter's earlier years, the orator was enabled to vindicate the great man from the charge which has been brought by so many former biographers of being during his youth inclined to waywardness, indolence, and dissipation. Moreover, in view of a present-day controversy, it is interesting to note that Holden concluded his oration by dwelling on the advantage of a classical training for medical students, stating that as an old teacher he found that those pupils who had received a good public school training could be taught more in two months than others in six. He urged that the youths who were to be the future representatives of English surgery should not be looked upon as "symbols" of an inferior education.

It is worthy of note that Luther Holden died in his ninetieth year, that he has a brother still living who is in his ninety-first year, and that the father and the mother of these two brothers were first-cousins. Luther Holden was a man of striking appearance. He was very tall and marvellously young for his years, carried himself very upright, and walked like a young man. He was always neatly dressed and markedly well turned out, and used to say himself, "I keep my youth by always being about with young people." After his retirement he took to travelling and went nearly all over the world—to Japan, South Africa, South America, and Australia. He was in Johannesburg in 1898 and when he came home he said, "Kruger won't live long, he's got emphysema and granular kidney." Wherever he went he was welcome and used to be entertained at dinner by old St. Bartholomew's men in out-of-the-way places. Luther Holden was twice married and when at home lived the life of a country gentleman on a small estate near Ipswich.

His body was interred in the cemetery of the parish church, Upminster, on Friday, Feb. 10th, the Rev. Hyla Holden, rector, officiating. The Royal College of Surgeons of England was represented by Mr. John Langton and St. Bartholomew's Hospital by Sir Dyce Duckworth and Mr. Harrison Cripps. Mr. T. B. Archer, Mr. Alban Doran (former house surgeons to Mr. Holden), Dr. J. H. Stowers, Dr. G. H. R. Holden of Reading, and many other relatives and friends of the deceased were present.

NATHANIEL DAVIDSON, L.R.C.P. LOND., L.R.C.S. EDIN., L.S.A.

ON Feb. 9th, at 11, Bentinck-terrace, Albert-road, London, N.W., one of the oldest members of the medical profession passed away in the person of Mr. Nathaniel Davidson. He was born in 1805 and would have completed his century if he had survived to the month of March. Mr. Davidson was educated at Edinburgh and took the Licence of the Royal College of Surgeons of Edinburgh in 1828. Coming to London he took the Licence of the Society of Apothecaries in 1829 and practised for many years in George-street, Portman-square. In 1861 he obtained the Licence of the Royal College of Physicians of London. The funeral took place at Shanklin, Isle of Wight, on Feb. 14th.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Gustave Piotrowski, *privat-docent* of physiology in the University of Lemberg.—Dr. I. Felix, formerly professor of hygiene in the Bucharest School of Medicine.—Dr. J. A. Serrano, professor of anatomy in the Lisbon medical school.—Dr. Gustav Ludwig, who was formerly physician to the German Hospital, London. Some ten years ago his health obliged him to give up practice and after travelling a good deal he settled down in Venice where he was able to enjoy his very considerable artistic and antiquarian collections.

MEDICINE AND THE LAW.

Analysts' Certificates under the Sale of Food and Drugs Acts.

AN appeal of a [illegible] recently heard in the Divisional [illegible] lyst's certificate in a case relating [illegible] The certificate impugned was as follows:—

[illegible] cent. of the milk-fat.

The justices had dismissed the charge on the ground that the certificate was bad in that it did not state the standard upon which it was based. The court dissented from this view after hearing argument on behalf of the public authority and ordered the case to be remitted to the magistrates. The Lord Chief Justice in giving judgment said that although the certificate showed that the milk had been compared with some standard it would have been more correct to state in it distinctly what the proper quantity of milk-fat was. Examination would reveal that this did appear from the certificate, or in other words "the standard of calculation could be gathered from the certificate itself," and for this reason the appeal was allowed. In agreeing with his lordship's view Mr. Justice Kennedy pointed out that it is important that the accused should know without elaborate calculations what he is accused of and he expressed the hope that those who gave certificates would err, if at all, on the side of fulness and simplicity. It is hardly necessary to add to this that the certificates of analysts in prosecutions under the Sale of Food and Drugs Acts are carefully scrutinised by the defence, not only in order to defeat the prosecution on technical grounds but in order that the defendant may be able to meet, if possible, the case raised against him and the objections to the form of the certificate are often made because it states too little, never because it says too much.

A Question of Professional Secrecy.

A paper read recently before the Obstetrical Society of Cincinnati, U.S.A., by Dr. E. S. McKee, had for its title "The Ethics of Gonorrhœa in the Female" and for its subject the difficulties which may beset the medical man in preserving the secrets of his patient consistently with his duty to society where venereal disease in a woman is concerned. In a case of this kind it is hardly necessary to point out that the knowledge acquired by the medical practitioner in the exercise of his profession is not confined to the fact that his patient suffers from a disease. It may place her reputation in his keeping, so that it is in his power to destroy it, or circumstances may come under his observation during his treatment of her which may render him the one person who can effectively maintain her honour. On some occasions, again, he may acquire the secret of the dishonour of a man or of a woman other than his patient. In short, the complications that may arise are numerous and each case must be dealt with according to its merits, always keeping in mind certain broad principles of professional conduct. In the paper referred to a curious instance is given of a case in which the duty of the medical man was not altogether clear and in which he had a legal decision to guide him with which he did not agree. A young man came to Dr. McKee and confessed that he had infected his wife with gonorrhœa. Dr. McKee successfully treated her for it. Meanwhile the husband confessed to his wife also what he had done and apparently allowed her to infer that her medical attendant knew to whom her disease was due. Later on divorce proceedings were initiated by [illegible] s equivalent [illegible] ons enforced [illegible] to what the [illegible] e American [illegible] the patient in the course of professional treatment but the judge decided that this did not apply to the evidence sought for in the instance before him on the ground that the wife was the patient and that the confidence, the revelation of which was sought, was not hers but her husband's. In England no privilege attaches so as to protect the medical man in any case but the principle upon which he resists the effort to extort from him in the witness-box the secrets of his patients is no doubt that upon which the American law was originally founded. If we regard the question decided by the judge as a matter of principle we shall see that the point is one not quite easy to determine offhand. The husband, no doubt, spoke in confidence to Dr. McKee and was entitled to have his communication jealously guarded. On the other hand, the wife was the patient and directly she alleged that she had contracted venereal disease and had been corroborated as to this by her medical attendant her honour was impugned unless she could show that her husband and no one else had infected her. Dr. McKee questions the soundness of the judicial decision and observes, probably correctly, that if he had attended the husband for gonorrhœa as well as the wife he could not have been ordered to give evidence on the subject. It may be considered, however, that on the question of principle the medical man is not bound to keep a secret which the person confiding it to him has himself given away, as he is in cases where his confidant has done his best to preserve it. The husband in Dr. McKee's case had told his secret to his wife and had apparently also told her or had allowed her to infer that he had told her medical adviser. In such circumstances he certainly had no right to complain if the medical man obeyed the judge's order without demur.

The Unlawful Detention of a Medical Man.

The Common Serjeant at the recent sessions of the Old Bailey disposed of a case which has been reported on two or three occasions in its earlier stages and which fortunately is of an unusual character. An obstetric assistant, Mr. Shrivell, having been summoned to attend a maternity case at a tenement in Spitalfields, found that the woman was not likely to be delivered immediately and prepared to leave, intending to return later, when he found that the household were not disposed to allow him to do so. Presumably they were afraid that he would not return and that the patient would suffer from his absence. They were aliens—very "undesirable aliens" from the medical man's point of view—and so were not amenable to the persuasion or threats that would have influenced the indigenous poor of the district and they were prepared to use force to bar his exit. The medical man in these circumstances submitted to be locked in, awaited the confinement of his patient, which took place in the course of the night, and when it had been brought to a satisfactory conclusion was allowed to leave. Afterwards, however, he applied, with the support of the hospital authorities, for legal process against his captors. The application was for an offence not often brought before criminal courts and was based upon facts of so unusual a character that Mr. Cluer before whom it was made had some doubt about granting a summons, and when it came on for hearing refused to dispose of the matter summarily. Accordingly the two persons responsible, a man and a woman named Lazarus Linsburg and Fanny Leiss, were indicted at the Old Bailey and pleaded guilty to counts in the indictment alleging imprisonment of the prosecutor. As to this charge the Common Serjeant ruled that imprisonment without a belief in the existence of a lawful cause for it (such as the belief that a felony has been committed) amounts to an assault at law without actual violence taking place. Mr. Bosanquet, however, did not think it necessary to treat the prisoners with severity, for he set them at liberty after binding them over to come up for judgment if called upon. There is a humorous aspect of their practical method of securing the presence of the medical man but at the same time it is to be hoped that the report of the case will have been circulated and read in the newspapers published by the various foreign communities of the East end and that such acts will not be repeated. The experience described has been stated not to be unique and to the gentleman imprisoned it must have been a source of annoyance and trouble. Moreover, if there had been considerable delay or if the case had developed unexpected features demanding communication with the outer world, or still more if through some untoward circumstance it had had a fatal termination, the position of the imprisoned medical attendant might have become a very awkward one.

Public Health and Poor Law.

LOCAL GOVERNMENT BOARD.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

The City of Aberdeen.—It is an interesting fact and one that illustrates in a remarkable fashion the progress of preventive medicine that typhus fever has now become so rare that outbreaks of it are worth recording. Dr. Matthew Hay in his report for the month of December last describes an outbreak of this disease which first came beneath his notice owing to the fact that a labourer who was believed to be suffering from measles and who was sent into hospital in consequence of delirium was found after admission to be suffering from typhus fever and a week later the patient's wife was admitted with similar symptoms. Again, two days after this a case of supposed enteric fever was notified and this on being examined proved to be another case of typhus fever. This patient had about 14 days' before he became ill attended upon two friends—a father and a grown-up son—both of whom had died, and it was found that the latter of these two patients had visited a family where there had been several cases of illness and where the father of the family had died in October last. This household had evidently been instrumental in spreading the disease and four of those who had visited this house were already dead. Altogether, up to the date of his report, Dr. Hay had discovered 40 cases and ten deaths. Curiously enough, one of the elementary schools was found to have been operative in spreading the disease among children. As Dr. Hay remarks, the fact that few medical men have seen typhus fever renders the diagnosis of the disease extremely difficult, more especially when, as in this instance, most of the cases occurred in the badly lighted and badly ventilated houses of the poor in circumstances which make it very difficult to determine the presence of the eruption peculiar to typhus fever. Fortunately, the hospital staff do not appear to have become infected and in this sense the disease manifested a marked contrast to its behaviour in the old days of the London Fever Hospital when medical officers, chaplains, and nurses were constantly succumbing to the disease. This outbreak is also instructive as illustrating how very misleading notification, when applied to a but rarely seen disease such as typhus fever, may prove.

The City of London.—Dr. W. Collingridge, in his report for December, 1904, and the first half of January, 1905, draws attention to the momentous subject of the importation of diseased pork from Denmark. It appears that up to the present there has been a sort of informal arrangement between the Danish Government and the City Corporation by means of which the attention of the Danes was called to any case of the condemnation in England of Danish meat. This arrangement was materially facilitated by the practice pursued in Denmark of attaching distinctive labels to meat, and when these labels were returned to Denmark owing to the meat labeled being bad it was easy for the Danes to follow up the matter. It was understood, however, that in such cases steps would be taken to remedy the evil. Unfortunately, although the label system has worked well with respect to beef, it does not appear to have prevented the arrival of pork in a condition unfit for human food, and Dr. Collingridge tells us that during the last three months of 1904 39 pigs were seized, while during the first half of January, 1905, no fewer than 49 were so condemned. It is apparently a common practice in Denmark to remove the thyroid glands and other parts of the carcass, a proceeding which considerably increases the difficulty of detecting diseased meat. Certainly, as the Danish authorities point out to Dr. Collingridge, it might be expected that tuberculosis of pigs would be rare in Denmark seeing that all skim milk has to be boiled in order to prevent the spreading of tuberculosis through this means. But be this as it may, a large number of tuberculous carcasses find their way into this country *viâ* Denmark, so much so, indeed, that Dr. Collingridge suggests the discontinuance of the return of the labels inasmuch as the labels do not now afford a proper guarantee of excellence.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 9001 births and 5220 deaths were registered during the week ending Feb. 11th The annual rate of mortality in these towns, which had been 18·1, 18·4, and 18·0 per 1000 in the three preceding weeks, further declined to 17·4 per 1000 last week. In London the death-rate was 17·6 per 1000, while it averaged 17·4 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 8·1 in Hornsey, 8·5 in Walthamstow, 9·2 in Smethwick, 9·3 in Handsworth (Staffs), 9·7 in East Ham, 10·9 in Croydon, and 11·8 in Leyton; while the highest rates were 24·2 in Hastings and in Rhondda, 24·6 in Norwich, 24·9 in Middlesbrough, 28·2 in Merthyr Tydfil, 29·0 in Hanley, and 29·8 in Stockton-on-Tees. The 5220 deaths in these towns last week included 401 which were referred to the principal infectious diseases, against 358, 376, and 368 in the three preceding weeks; of these 401 deaths, 110 resulted from whooping-cough, 100 from measles, 72 from diphtheria, 47 from diarrhœa, 45 from scarlet fever, 24 from "fever" (principally enteric), and three from small-pox. In Hornsey, Brighton, Wolverhampton, Coventry, Derby, Halifax, York, Swansea, and in ten other smaller towns no death from any of the principal infectious diseases was registered, while they caused the highest death-rates in Southampton, Hanley, Nottingham, Burnley, Stockton-on-Tees, West Hartlepool, Rhondda, and Merthyr Tydfil. The greatest proportional mortality from measles occurred in Leyton, Portsmouth, Southampton, Reading, Nottingham, Stockton-on-Tees, West Hartlepool, Cardiff, and Merthyr Tydfil; from scarlet fever in Northampton and Stockton-on-Tees; from diphtheria in East Ham, [illegible] Tydfil; fro [illegible] Hastings, I [illegible] l Merthyr Tydfil; from "fever" in Devonport; and from diarrhœa in Burnley. Of the three fatal cases of small-pox registered in these towns last week one belonged to Oldham, one to Burnley, and one to Bradford. The number of small-pox patients in the Metropolitan Asylums Hospitals, which had been 18, 15, and 13 at the end of the three preceding weeks, had further declined to nine at the end of last week; one new case was admitted during the week, against one, none, and one in the three preceding weeks. The number of scarlet fever cases remaining under treatment in these hospitals and in the London Fever Hospital on Saturday, Feb. 11th, was 2077, against 2174, 2096, and 2070 at the end of three preceding weeks; 260 new cases were admitted during the week, against 225, 251, and 229 in the three preceding weeks. The deaths in London referred to pneumonia and diseases of the respiratory system, which had been 377, 478, and 444 in the three preceding weeks, further declined to 400 last week, but were 76 in excess of the number in the corresponding period of last year. The causes of 54, or 1·0 per cent., of the deaths in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Portsmouth, Bristol, Nottingham, Leeds, Newcastle-on-Tyne, and in 47 other smaller towns; the largest proportions of uncertified deaths were registered in Ipswich, Liverpool, Warrington, Blackburn, and South Shields.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 20·1, 20·3, and 19·9 per 1000 in the three preceding weeks, further declined to 18·2 per 1000 during the week ending Feb. 11th, but was 0·8 per 1000 in excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 13·4 in Paisley and 14·7 in Leith to 21·3 in Perth and 22·7 in Aberdeen. The 612 deaths in these towns included 23 which were referred to whooping-cough, nine to diarrhœa, seven to measles, five to "fever," three to diphtheria, and two to scarlet fever. In all, 49 deaths resulted from these principal infectious diseases last week, against 72, 79, and 85 in the three preceding weeks. These 49 deaths were equal to an annual rate of 1·5 per 1000, which was 0·2 per 1000 above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of whooping-cough, which had been 33, 44, and 46 in the three preceding weeks, declined again last week to 23, of which 17 were registered in Glasgow and three in Edinburgh. The deaths from diarrhœa, which had been 17, nine, and 19 in the three preceding weeks, declined again to nine last week and included four in Glasgow, three in Edinburgh, and two in Leith. The fatal cases of measles, which had been six in each of the two preceding weeks, increased last week to seven, all of which occurred in Glasgow. The deaths from "fever," which had been six and four in the two preceding weeks, rose again to five last week and included four in Glasgow. The fatal cases of diphtheria, which had been nine in each of the two preceding weeks, decreased last week to three, of which two occurred in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 156, 163, and 146 in the three preceding weeks, further declined last week to 130, but were slightly in excess of the number in the corresponding period of last year. The causes of 19, or more than 3 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 21·2, 25·5, and 24·2 per 1000 in the three preceding weeks, rose again to 25·2 per 1000 during the week ending Feb. 11th. During the past four weeks the death-rate has averaged 24·0 per 1000, the rates during the same period being 17·7 in London and 19·6 in Edinburgh. The 183 deaths of persons belonging to Dublin registered during the week under notice were seven in excess of the number in the preceding week and included seven which were referred to the principal infectious diseases, against 10, 18, and nine in the three preceding weeks; of these, three resulted from diarrhœa, two from scarlet fever, and two from "fever," but not any from small-pox, measles, diphtheria, or whooping cough. These seven deaths were equal to an annual rate of 1·0 per 1000, the death-rates last week from the principal infectious diseases being 1·3 in London and 0·8 in Edinburgh. The 183 deaths in Dublin last week included 27 among children under one year of age and 45 among persons aged 60 years and upwards; the deaths both of infants and of elderly persons showed a marked decline from the respective numbers recorded in the preceding week. Nine inquest cases and five deaths from violence were registered; and 60, or nearly one third, of the deaths occurred in public institutions. The causes of four, or more than 2 per cent., of the deaths in Dublin last week were not certified.

VITAL STATISTICS OF LONDON DURING JANUARY, 1905.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious disease it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 5·8 per 1000 of the population, estimated at 4,684,794 persons in the middle of the year. In the three preceding months the rates had been 9·0, 7·2, and 6·1 per 1000. The rates were considerably below the average in Paddington, Kensington, the City of Westminster, St. Marylebone, Hampstead, Stoke Newington, and the City of London, while they showed the largest excess in Hammersmith, Hackney, Bethnal Green, Stepney, Poplar, Wandsworth, and Woolwich. The prevalence of small-pox showed a marked decline last month; of the four cases of this disease notified during January, two belonged to Woolwich and one each to Shoreditch and Lewisham. The Metropolitan Asylums hospitals contained 15 small-pox patients at the end of last month, against one, three, and 17 at the end of the three preceding months; the weekly admissions averaged one, against none, one, and four in the three preceding months. Scarlet fever was slightly less prevalent last month than in other recent months; among the various metropolitan boroughs this disease showed the highest proportional prevalence in Chelsea, Hackney, Bethnal Green, Wandsworth, and Lewisham. The number of scarlet fever patients under treatment in the Metropolitan Asylums hospitals at the end of the month was 2067, against 2662, 2566, and 2349 at the end of the three preceding months; the weekly admissions averaged 209, against 359, 249, and 233 in the three preceding months. The prevalence of diphtheria during January was in excess of that recorded in the preceding month; this disease was proportionally most prevalent in Hammersmith, Fulham, Hackney, Bethnal Green, Stepney, Poplar, and Woolwich. The Metropolitan Asylums hospitals contained 836 diphtheria patients at the end of last month, against 940, 893, and 800 at the end of the three preceding months; the weekly admissions averaged

* Including membranous croup.

115 against 139 123 and 99 in the three preceding months The prevalence of enteric fever showed a considerable decline last month , among the various metropolitan boroughs the greatest proportional prevalence of this disease occurred in Hackney Finsbury Shoreditch Bethnal Green Stepney and Battersea The number of enteric fever patients in the Metropolitan Asylums hospitals, which had been 225 178 and 237 at the end of the three preceding months had declined again to 134 at the end of last month, the weekly admissions averaged 17, against 25 25 and 22 in the three preceding months Erysipelas was proportionally most prevalent in St Marylebone Hackney, Bethnal Green Stepney, Battersea and Deptford The 23 cases of puerperal fever notified during the month included three in Hammersmith three in Fulham three in Wandsworth three in Camberwell *and three in Woolwich*

The mortality statistics in the table relate to the deaths of persons actually belonging to the various metropolitan boroughs, the deaths occurring in public institutions having been distributed among the several boroughs in which the deceased persons had previously resided During the four weeks ending Jan 28th the deaths of 6092 persons belonging to London were registered equal to an annual rate of 17 0 per 1000 , in the three preceding months the rates had been 14 3 14 6 and 18 4 per 1000 The lowest death rates in London last month were 8 7 in Hampstead 13 7 in Wandsworth and in Lewisham 13 8 in Deptford 13 9 in Hammersmith and 14 3 in Hackney , the highest rates were 20 3 in St Pancras 20 4 in Poplar 21 4 in Bermondsey, 21 9 in Bethnal Green 23 2 in Finsbury, 24 7 in Holborn and 26 2 in the City of London The 6092 deaths from all causes included 361 which were referred to the principal infectious diseases of these two resulted from small pox 107 from measles 39 from scarlet fever, 51 from diphtheria 100 from whooping cough 19 from enteric fever and 43 from diarrhœa The lowest death rates from these diseases occurred in Paddington the City of Westminster St Marylebone, Hampstead Lambeth Deptford Greenwich and Lewisham , and the highest rates in Fulham Finsbury, Shoreditch Stepney Poplar and Bermondsey Of the two deaths from small pox one belonged to Shoreditch and one to Lewisham The 107 fatal cases of measles were 98 below the average in the corresponding periods of the ten preceding years this disease was proportionally most fatal in Fulham Hackney Finsbury Shoreditch Poplar Bermondsey, and Wandsworth The 39 deaths from scarlet fever showed a decline of 13 from the corrected average number , among the various metropolitan boroughs this disease showed the highest proportional mortality in Stoke Newington Finsbury Shoreditch Bethnal Green Bermondsey and Lambeth The fatal cases of diphtheria numbered 51 last month against an average of 147 in the corresponding period of the ten preceding years , the highest death rates from this disease occurred in Hammersmith Bethnal Green Stepney Poplar Southwark and Woolwich The 100 deaths *from whooping* cough were 74 below the corrected average number , among the various metropolitan boroughs this disease was proportionally most fatal in Hammersmith Fulham Chelsea Shoreditch Southwark and Bermondsey The 19 fatal cases of ' fever showed a decline of 31 from the average number in the corresponding periods of the ten preceding years , the highest fever death rates occurred in St Pancras Holborn Finsbury Shoreditch Stepney and Bermondsey The 43 deaths from diarrhœa were slightly below the [illegible] ns [illegible] y [illegible] ay [illegible] th [illegible] per [illegible] by the proportion of deaths [illegible] r of age to registered births [illegible] The lowest rates of infant mortality were recorded in Hammersmith St Marylebone Hackney Bermondsey Battersea Wandsworth Greenwich and Lewisham , and the highest rates in Chelsea Stoke Newington, Shoreditch, Bethnal Green Poplar, and Southwark

THE SERVICES

ROYAL NAVY MEDICAL SERVICE

THE following appointments are notified —Fleet Surgeon A E Weightman to the *Spartiate* Staff Surgeons H P Jones to the *Hermes* on commissioning , P K Nix to the *Blake* A W B Livesay to R M Depôt, Deal , and H W G Green to the *Dido* on recommissioning Surgeons A J Hewitt to R M A Barracks Eastney , P F Alder on to Plymouth Hospital , F M V Smith to the *Dido* on recomm [illegible] C D Walsh to the *Scylla* for the [illegible] Surgeon J Brunt is placed o [illegible] seniority of Oct 1st, 1879

Deputy Inspector General of Hospitals and Fleets Gerard James Irvine has been promoted to the rank of Inspector General of Hospitals and Fleets in His Majesty s Fleet Fleet Surgeon Arthur William May has been promoted to the rank of Deputy Inspector General of Hospitals and Fleets in His Majesty s Fleet (dated Feb 7th 1905)

The undermentioned Surgeons have been promoted to the rank of Staff Surgeon in His Majesty s Fleet —Alexander George William Bowen and George Ley (dated Nov 11th, 1899), Robert Dundonald Jameson (dated May 16th, 1902) , William Bernera Macleod Harry Spicer and John Alexander Lanford Campbell (dated Nov 14th 1902) Herbert Henry Pearse and Charles James Edward Cock (dated May 15th, 1903) John William Craig (dated May 13th 1904) , and Edwyn Robert Grazebrook (dated Nov 10th, 1904)

ROYAL ARMY MEDICAL CORPS

Lieutenant Colonel J G Harwood is appointed to the Southern District on the retirement of Lieutenant Colonel P J Dempsey Captain P J Bodington is posted to the Home District for duty on arrival home from Ceylon Captain H H Norman has left Woolwich Lieutenant S M Adye Curran is placed on temporary half pay on account of ill health

Lieutenant Colonel G D Hunter, D S O is seconded for service with the Egyptian Army (dated Feb 2nd 1905)

The undermentioned Captains to be Majors (dated Jan 30th 1905) —C T Samman H A Berryman C G Spencer C E P Fowler T H J C Goodwin D S O, A T C Keble D J Collins and J B Anderson Captain R T G Phillips from the Seconded List to be Captain (dated Feb 1st 1905) Lieutenant R G Anderson from *the Seconded List* to be Lieutenant (dated Jan 30th, 1905)

VOLUNTEER CORPS

Royal Garrison Artillery (Volunteers) 1st East Riding of Yorkshire Surgeon Lieutenant Colonel W Draper is granted the honorary rank of Surgeon Colonel (dated Feb 11th 1905)

Rifle 4th Volunteer Battalion the Devonshire Regiment Surgeon Major J R Thomas (Brigade-Surgeon *Lieutenant Colonel* Senior Medical Officer Devon Volunteer Infantry Brigade) to be Surgeon Lieutenant Colonel (dated [illegible] 1905) Surgeon Lieutenant Colonel J R Thomas ([illegible] Medical Officer [illegible] ted the honorary rank of Surgeon Colonel (dated Feb 11th 1905) 2nd Volunteer Battalion the East Surrey Regiment Surgeon Lieutenant Colonel W Gandy (Brigade Surgeon Lieutenant *Colonel* Senior Medical Officer East Surrey Volunteer Infantry Brigade) is granted the honorary rank of Surgeon *Colonel* (dated Feb 11th 1905) 1st Volunteer Battalion the Essex Regiment Surgeon Lieutenant J Aitken to be Surgeon Captain (dated Feb 11th 1905) 13th Middlesex (Queen s Westminster) Surgeon Captain W Rose resigns his commission (dated Feb 11th 1905)

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS)

The London Companies Lieutenant H S Collier resigns his commission (*dated Feb* 11th 1905)

DEATHS IN THE SERVICES

Surgeon Major General Thomas Walsh A M S (retired), on Feb 7th at his residence Mer Vue Booterstown county Dublin He entered the service as an assistant surgeon in 1858 became surgeon in March 1873 and surgeon major a month later brigade surgeon in 1884 surgeon colonel in 1889 and surgeon major general in 1894 He was employed with the Jowaki Afridi expedition of 1877 78 and in the Afghan war in 1879 80 As *senior medical officer in the* latter expedition he did some good work for which he was *mentioned* in despatches In the Egyptian war of 1882 he was sanitary officer to the 1st Division and was present at the engagement at Tel el Mahuta at *the action at* Kassassin, and at the battle of Tel el Kebir

THE WAR IN THE FAR EAST.

The sufferings of the troops at the front from the extreme cold have been indescribable but the weather has recently become much warmer. According to the latest accounts from Manchuria the thermometer during the day registered only three degrees of frost. There is considerable difficulty in ascertaining what is the exact truth about the supplies of the Russian forces in the field; the accounts are conflicting, but it may be safely concluded that the position of the large Russian army in Manchuria, dependent on the Trans-Siberian railway only, must be a precarious one. Nor is this the only subject on which the accounts are so conflicting as to be irreconcileable with one another. Those regarding the state of Port Arthur at the end of the siege, and especially as to the number of sick and wounded in hospital at that time as now given by General Stoessel, are quite at variance with the statements previously made by others. There have been no military movements of importance on the part of the belligerent forces during the week. The rumours of peace continue but whether they have any foundation beyond the fact that everybody would be glad to hear that an end had come at last to the terrible loss of life and suffering is more than anyone can say. Both sides have suffered heavily by the war but the losses on the part of the Russians in men, money, and *matériel*, and still more perhaps in prestige, have been simply enormous. It is a consideration of the whole history of the war and of her present situation that makes it so difficult for the Russian Government to approach the Japanese with any proffered terms of peace at the present time.

The Kwangschan correspondent of the *Novoe Vremya* quotes statistics of the Manchurian army sanitary bureau relating to infectious diseases, showing that the sanitary state of the army was remarkably satisfactory on Jan. 21st. There were only 156 cases of dysentery, 752 cases of "abdominal typhus," 32 of "eruptive typhus," 15 of "recurrent typhus," and 3 of typhus not classified, 198 of influenza, 1 of epidemic gastritis, 35 of intermittent fever, 44 of Siberian plague, 51 of erysipelas, 3 of scurvy, 4 of small-pox, 1 of measles, and, finally, 205 of diarrhœa. The whole army is supplied with warm clothing. The nourishment is without question good and even at the outposts hot food is served twice daily. The only bad point is the difficulty in furnishing the army with fuel. The chief representative of the special Red Cross Committee, A. J. Gutchkoff, telegraphs from the Far East that on making a round of the positions the medical men of the detachment dealing with infection have declared that in view of the excellent sanitary condition of the army an "anti-contagion" detachment is required only in Kharbin where there are 35,000 hospital beds. In the spring two flying detachments will probably proceed to the south.

A report from Kharbin of Jan. 5th states that there are few invalids in the hospitals of the Red Cross Society. There is no epidemic disease in the town. The hospital of the society is comfortably installed in the best communal building in Kharbin. The confidence and activity of the staff insure perfect order.

Correspondence.

"Audi alteram partem."

MEDICAL TEACHING IN THE METROPOLIS.

To the Editors of THE LANCET.

SIRS,—Your leading article on the above subject published in THE LANCET of Feb. 11th prompts me to call attention to the fact that one branch of medical teaching in our London medical schools stands in sad need of stimulation. All will agree that clinical surgery is well taught in the London schools, but the like cannot, I fear, be said of clinical medicine. In spite of the learning and skill of our London physicians few of them, alas, are experts in the art of imparting that knowledge and that skill, for, unhappily, the possession of knowledge and the ability to impart it are not one and the *same thing*, and of no branch of knowledge is this more true than of clinical medicine.

How are we to account for this dearth of good clinical teachers? It is mainly owing to the fact that in the election of physicians to teaching hospitals due regard is not had to their teaching capabilities. This is as mistaken in policy as it is wrong in principle. The ability to teach is a more necessary qualification in the member of the staff of a teaching hospital than a brilliant academic career. On him devolves, as member of the staff, a double duty—not only the exercising of his craft but the teaching others how to exercise that craft, and in proportion as he succeeds in these must his election be deemed to have been a wise one. To suppose that his teaching duties are merely accessory to his duty as physician is to form an altogether wrong conception of his position. He is under a grave obligation not only to do his best by his patients but also by his pupils—to arm them with the means by which they may do successful battle against disease—and thus extend the benefits he confers on humanity far beyond the narrow confines of his hospital.

Under the present system of election it is impossible to be certain of securing the best clinical teachers, inasmuch as little or no opportunity is afforded the young physician prior to his election of demonstrating his teaching capabilities, and once elected he remains on the staff till age, death, or inclination (seldom vouchsafed) removes him from the scene, mounting up the ladder of promotion on the very simple, but most pernicious, principle of seniority. No concern run on these lines—commercial, medical, or any other—can achieve its full measure of success. In each and all and always every facility should be given for the right men to come to the front. "Catch your capable men," as Huxley tersely puts it, should be a guiding principle in every department of human activity. The system of permanent election not only exposes the schools to the danger of being saddled with inefficients, but makes no provision against men "going off" prematurely, for it is a strange and unhappy fact that just as some women lose their beauty after the first flush of youth so some men who start with every apparent prospect of brilliant success somehow or other soon begin to lag behind and finally drop out of the ranks of serious competition: they cease to develop, enthusiasm and initiative wane, the plastic cerebral protoplasm hardens all too soon, and the brilliant forceful man of yesterday becomes the stolid, uninspired platitudinous individual of to-day. He has failed to realise the expectations formed of him and is no longer fit for the position he holds. We are all sorry for him, but our sympathy for him must be tempered by our sense of duty to others and not blind us to the fact that he is no longer the right man in the right place, and that by allowing him to continue in it we are doing a grievous wrong to others, to many others—I mean the students, and thus through them to a large section of the community.

How can we best meet these difficulties? Obviously by a system of provisional election. Assistant physicians should be elected for a certain term and on a distinct understanding that if at the end of that term they have failed to realise expectations they will not be re-elected. Their ability as teachers can be gauged with mathematical precision—i.e., by the following they get among the students. A careful daily record should be made of the number of students attending the out-patient and in-patient departments of every member of the hospital staff, and these records should be given prominent publicity every three months. This plan would not only enable an estimate of individual teaching capacity to be formed, but tend to promote a healthy rivalry in clinical teaching, stimulating every member of the staff to perfect himself as a teacher and compelling him to realise that clinical teaching is not only a great and noble but likewise a very difficult art, one in which efficiency can be attained only after long and painstaking cultivation.

You, Sirs, give expression in your article to the belief "that in the near future every hospital will be found able to supply numerous junior appointments for those who desire occupation and opportunity of demonstrating their powers of teaching." A consummation devoutly to be wished, and to the furtherance of which I would suggest the advisability of appointing to each of the larger hospitals two or more posts of sub-assistant physician, tenable, say, for one year, and affording the holders ample facility for demonstrating selected patients to students. I believe it would also be a good plan for the great schools to throw open their doors to clinical teachers from other hospitals than their own. There are not a few capable men in London connected with non-teaching hospitals. Could not some arrangement be come to by which their services might be utilised in the schools? A further plan of improving the teaching of clinical medicine in London would be to do away with systematic lectures on medicine and to give in their stead systematic demonstrations of selected patients. The kind of information it is sought to convey in lecture can be much better taught in tutorial class.

Finally, I would make it obligatory for every candidate for a post on the permanent medical staff of a teaching hospital to have spent one year in special study (as clinical clerk or otherwise) at each of the special departments for diseases of the eye, skin, and the nose and throat; two years at a special hospital for children's diseases, and another two years at a special hospital for diseases of the nervous system. At any cost the great hospitals must exclude the medical exclusivist. By such means as these I believe that much might be done to improve the teaching of clinical medicine in London and to raise it to a position worthy of the world's great metropolis.

I am, Sirs, yours faithfully,

Wimpole-street, W., Feb. 12th, 1905. HARRY CAMPBELL.

THE BUILDING BY-LAWS.

To the Editors of THE LANCET.

SIRS,—In the reference you have been good enough to make in your leading article on the above subject in your issue of Feb. 11th, p. 369, to my letter in the *Times* you suggest that the difficulty to which I drew attention as to the incongruity of the terms "urban" and "rural" in their application to sanitary districts and the need for the remedy I proposed of discontinuing this distinction of districts and applying it to the houses themselves are to some extent met by the greater latitude which the Local Government Board now allows to district councils in regard to the adoption of either urban or rural by-laws to portions only of their districts. But I think you will see upon consideration that the remedy is a very imperfect one because it entails the necessity of defining the boundaries of the portions of the district to which the urban or rural powers shall apply, always a serious difficulty, and one which would perpetually require revision in growing districts in order to meet altering requirements.

My proposal of dealing with a house as urban or rural, according to the width of its curtilage, gets over this difficulty altogether. At present all building by-laws, I believe, prescribe that a certain space shall be kept uncovered in front of, and behind, the premises to be erected. My proposal would involve a similar restriction on each side of the premises if they were to be erected under rural by-laws, and in that case would leave the builder a considerable amount of latitude as to the construction of his house, so long as he complied with certain indispensable requirements as to drainage, water-supply, disposal of dry refuse, dryness of foundations and walls, &c. But if he were unable to satisfy the minimum condition of circumjacent space and, of course, if he proposed to erect two or more dwellings in actual contact with one another, then he would come under the more rigid control of urban by-laws. The provision is one that would obviously work automatically. There would be no necessity for any Local Government Board inquiry, no definition of boundaries would be required. Whether the site of the proposed house were in a large city or in the midst of a wood the sole question would be, What is the size of your curtilage? And it is clear that it would have to be large enough to allow the whole of the refuse of the probable occupants of the house to be dealt with on their own premises, if necessary, and in such a way as not to create a nuisance to their neighbours.

It would not be necessary, as you seem to think, that a house erected under rural by-laws should remain always detached. But if its owner wished to build another in connexion with it or within the prescribed distance he would only be able to do so on condition that he brought his old house up to the urban standard in all conditions. If it were originally substantially built this would not probably involve serious outlay, but if it were of the bungalow type or jerry-built, though apparently substantial, he would probably find it cheaper to pull it down altogether. The only person who would have to provide against the contingency you cite of a road originally bordered by rural villas which becomes gradually converted into streets of continuous bricks and mortar would be the individual who might originally erect the suburban villas or those who might purchase them from him. Each would have to look ahead and consider how far his future interests [illegible] of building which [illegible] the houses to urban [illegible] sation should make such a change advantageous. My proposal, therefore, is not to do away with building by-laws but to differentiate them into two categories, as at present, which shall be automatically applicable to any house according to the amount of land by which it is to be surrounded.

I am, Sirs, yours faithfully,

Gloucester. FRANCIS T. BOND, M.D. Lond.

DUODENAL ULCER

To the Editors of THE LANCET.

SIRS,—There are one or two points in Mr. B. G. A. Moynihan's interesting paper on Duodenal Ulcer in THE LANCET of Feb. 11th, p. 340, on which one would be glad to have further information. He speaks in his present paper as well as in the one which you published in December, 1901, of the mimicry of appendicitis, which is referred to by various authors. What one would like to know is whether he has observed it himself in cases of perforation. Personally I have not except in one case which I did not see until some time after it occurred. I fancy this statement depends on the fact that before attention had been called to the frequency of duodenal perforation the necessity for early operation was overlooked; but now that such cases, largely owing to Mr. Moynihan's writings, are earlier recognised and more promptly treated the diagnosis has become easier and the mimicry of appendicitis is consequently rare.

When an attack of sudden and violent abdominal pain associated with collapse is accompanied, say, two or three hours later by lack of movement of the right rectus above the umbilicus, coupled with localised pain and tenderness referred to the same spot, a ruptured gastric or duodenal ulcer is certainly to be inferred, and if the rupture be in the stomach and not in the duodenum it will not be more than about one inch from the pylorus. At least that is my experience, and this symptom is due, I fancy, not so much to the "colon hillock" as to the attachment of the mesentery which largely influences the direction that the effused contents follow. No mention is made of flushing in order to rid the abdomen of the intestinal contents in this present paper. It would be interesting to know if Mr. Moynihan still advocates it. I have long since discarded it in all ruptured gastric and duodenal ulcers and I am sure my results have been better since.

I am, Sirs, yours faithfully,

Harley street, W., Feb 13th, 1905. W. BRUCE CLARKE.

PULMONARY TUBERCULOSIS AND ITS ASSOCIATIONS.

To the Editors of THE LANCET.

SIRS,—The interesting annotation upon tuberculosis in Nottinghamshire calls surprised attention to pulmonary tuberculosis being more fatal in rural than in urban districts. In THE LANCET of April 15th, 1899, p. 1005, and in the museum catalogue of the British Congress on Tuberculosis the greater fatality of phthisis in the country compared to towns is pointed out. It was a feature of the disease up to middle life and was to be observed as a general rule all over England 1881–90. I desire to draw attention to the value of even slight analysis in proclaiming the lines of incidence of this disease, so necessary a precursor of useful prophylaxis. The city of Nottingham report for the same year (1903) affords a good example.

Tuberculosis Mortality per 1000 living at Ages over 15 years.

Men, occupied	2·408	Women, occupied...	0·881
" unoccupied	1·377	" unoccupied	1·5

The public cannot be expected to read a multitude of figures, but if they get a high value from an analysis such as urban and rural it is evidently much higher when carried on to the distinctions in age and sex as above. Every medical officer will take the social, economic, or hygienic classification he finds best. My excuse for troubling your columns is the great want of classifications to guide us in the direction most promising for the prevention of tuberculosis.

I am, Sirs, yours faithfully,
Feb. 13th, 1905. HUGH R. BEEVOR.

FORMOLYPTOL IN DIPHTHERIA.

To the Editors of THE LANCET.

SIRS,—About two months ago a note was published in THE LANCET on the successful use of mulyptol locally for diphtheria and a week or so after that I was called to see a child, aged 11 years, whom I found complaining of her throat, which her mother said had been sore for 12 hours. She had a temperature of 104·4° F. and both tonsils and the back of the fauces were covered with a thick ashy-grey membrane. I had already sent a child from the family above (it was a tenement house) into the South Devon Hospital for tracheotomy with what proved laryngeal diphtheria and I was told that another child had died in the house from "acute bronchitis." I endeavoured to get some mulyptol but could only get formolyptol, which I used as a spray and also a gargle, besides administering two-minim doses internally. The temperature subsided in 24 hours, the throat cleared up rapidly, and the child was out of all danger in less than two days. Dr. W. L. Pethybridge, pathologist to the hospital, kindly made a culture from a swab and found the diphtheria bacillus. I was most agreeably surprised at the efficacious and rapid way in which the formolyptol acted and hope this note may be useful to those who may have to treat a similar condition.

I am, Sirs, yours faithfully,
C. E. RUSSEL RENDLE,
Feb. 11th, 1905. Assistant Surgeon, South Devon Hospital.

COFFEE AND SEWAGE.

To the Editors of THE LANCET.

SIRS,—Your editorial remarks on the recent decision of Mr. Chapman in the case of the coffee salvaged from the s.s. *Caravellas* are evidently made upon the basis of a very imperfect report of the evidence and are, therefore, I venture to think, a little unfair. I feel sure that I can appeal to your well-known justice to all parties for a hearing so that the facts may be better understood than they have been.

At the hearing of the case I produced evidence and specimens to show: 1. That coffee during roasting attains a temperature of about 180° C., or 356° F., which is maintained for a long time. 2. That before reaching this it remains for a considerable time at or near 100°-103° C. (212°-218° F.), during which time much vapour of water is given off. 3. That after a period of rest or even slight fall of temperature this again advances; various oils and acid products, together with water from the breakdown of the berry by heat, are given off and the berry swells and softens. Its loss in weight is from 15 to 20 per cent. on the dry coffee. 4. The sanitary officials admitted that organisms, pathogenic or not, would not survive this heat coupled with the vapours present. 5. Carefully made cultivations were made from the coffee received from the roasters in the roasted state and no growth of any kind ensued. The roasted berries were quite sterile. It was suggested that toxins produced by the organisms might be present but no evidence of their existence was before the court and I need not enlarge on the improbability of their presence in the roasted coffee.

I also venture to deprecate the use of the term "sewage soaked." I am informed that the ship was sunk between Coalhouse Point and Cliffe, some two miles below Gravesend. The water is no doubt contaminated but it is not fair to call it "sewage." If every bag of sugar, chest of currants, bag of wheat, &c., that got well wetted by such water were condemned there would be enough for the sanitary officers to do. But such things, it is well known, are not stopped, though sugar at least, which is used as often as not without cooking, is far more dangerous than green coffee. It was the fact that it had heated and showed signs of mould that caused the seizure. The sewage suggestion appeared to be an afterthought.

Pray understand that my remarks apply only to the particular lot of 60 tons with which I dealt. I saw no specimens of that condemned elsewhere and express no opinion on their state. It is obvious that green coffee wetted with perfectly good water would ferment and rot in time.

I am, Sirs, yours faithfully,
Feb. 11th, 1905. R. J. FRISWELL.

*** Mr. Friswell is, of course, entitled to his opinion but we may remind him that pollution is not necessarily of a bacteriological kind. The water of the river at the points mentioned is in his own words "no doubt contaminated," whether it be fair or not to call it sewage, and the coffee had been admittedly soaked in this water. No one, we imagine, would relish the idea of drinking water polluted with sewage effluent even if sterile.—ED. L.

CURRENT THEORIES OF THE HEREDITARY PROCESS.

To the Editors of THE LANCET.

SIRS,—In the annotation on the above subject in THE LANCET of Feb. 4th, p. 307, the following statement occurs:—

> Both these writers [Boveri and Delage] have shown that denucleated eggs produced by mechanical extrusion of nuclei can be fertilised in the sea urchin and that they give rise to normal blastulæ, gastrulæ, and larvæ. Hence the "determinants" of heredity are present in the cell body of the egg.

Surely this is a false conclusion, since no notice is taken of the nucleus of the spermatozoon. The fact that if fertilisation is effected by alien spermatozoa the resulting larvæ show purely paternal characters is a very strong argument in favour of Weismann's view that the nucleus is the vehicle of hereditary transmission. There is no evidence in these experiments that the cytoplasm of the ovum plays any part at all in the transmission of hereditary characters.

I am, Sirs, yours faithfully,
CHARLES POWELL WHITE.
St. Thomas's Hospital, Feb. 7th, 1905.

*** From the experiments referred to two entirely opposite conclusions are drawn—viz., that attributed to Professor W. F. R. Weldon, F.R.S., in our issue of Feb. 4th, and that to which Mr. Powell White alludes above. These interpretations are still the subject of discussion. Boveri himself admits that the "merogonie" experiments are equivocal because bastard larvæ, arising by the union of an entire egg with the spermatozoon of a distinct species, may also present the pure paternal form. At the same time, referring to the criticism raised by Pfeffer and others that the spermatozoon is an entire cell and not merely a nucleus, he points out that this argument is not admissible in appraising the part played by the egg protoplasm in fertilisation. In bastard larvæ which have obtained nuclear substance only from the spermatozoon in the fertilisation of egg fragments without nucleus ("merogonie") the paternal type appears exclusively (*vide* Boveri: "Ergebnisse ueber die Konstitution des Zellkerns," Jena, 1904, pp. 104, 105).—ED. L.

COUGH DUE TO INTESTINAL WORM.

To the Editors of THE LANCET.

SIRS,—The extraordinary case of reflex lumbrical irritation contributed to THE LANCET of Jan. 28th by Mr. Prosper St. Leger Liston reminds me of a somewhat similar pathological picture painted by the father of one of my patients in the first half of the last century. There is one striking difference however; for the main figure in the sketch, by Dr. R. J. Graves of Dublin, to which I allude, was a Tænia instead of an Ascaris lumbricoides, otherwise the title of Mr. Liston's case would have served for that of Dr. Graves. The latter physician was not as fortunate as the former; he did *not* make out *his* case but suffered the humiliation of being "scored off" by an unqualified lady doctor.

Dr. Graves's case was one of "severe cough and loss of weight due to tapeworm in the intestine." The details are much too instructive to be lost. A young woman attacked with symptoms of violent and alarming "bronchitis" was attended by a friend of Dr. Graves. When seen by the latter he found that the fits of coughing went on for hours with extraordinary intensity. The cough was dry, noisy, hollow, and incessant, repeated every five or six seconds during sleep at night as well as during the day. The violence was such that it threatened to "tear her chest in pieces." Her friends wondered how any frame could withstand so constant and terrible an agitation. Yet there was no fever, the chest exhibited nothing but the ordinary râles of what was in those days called "dry bronchitis," and the loss of flesh was by no means commensurate with the apparent gravity of the condition. This unfortunate girl was bled, leeched, blistered, and antimonialised without the slightest relief. She then had antispasmodics galore but with no effect. Next every species of narcotic was administered without the very faintest benefit. Then, fortunately, her physicians discontinued their visits and the case was taken up by an old retainer in the family. This old woman suggested a full dose of turpentine with castor oil for the relief of colic. '*In two or three hours a large mass of tapeworm was passed and every symptom disappeared.* Robert J. Graves was the soul of sincerity. How few men would have had the courage to narrate such a failure as occurring in their own practice. What a lesson in frankness and humility! In treating any cough how needful it is to remember that we can cough from irritation of any portion of the body supplied by the great vago-sympathetic; and what part of the body is not supplied by [illegible] been treated without ar[illegible]s? At p. 32 of my small work on Eczema I have described a persistent dermatitis of the navel in a child which resisted months of treatment and was then suddenly cured by santonin given to expel a round worm.

I am, Sirs, yours faithfully,
EDWARD BLAKE, M.D. Aberd., &c.
Seymour-street, W., Jan. 23th, 1905.

MOSQUITOES AND MALARIAL FEVER.

To the Editors of THE LANCET.

SIRS,—Not seeing the subject mentioned in THE LANCET I forward to you an extract from the *Times* of Feb. 8th which is not without general interest. It is from "our own correspondent," Colombo, and is as follows:—"Sir H. A. Blake, Governor of Ceylon, announced at a meeting of the Asiatic Society that Sinhalese books of the sixth century described 67 varieties of mosquitoes and 424 kinds of malarial fever caused by mosquitoes."

Putting aside the question of numbers the association of these insects in causation in days long gone past is a matter which seems worthy of notice in present medical literature and the record of it may lead some of those who may have the opportunity to dip more into the subject as detailed in these old books.—I am, Sirs, yours faithfully,

FRANCIS H. WELCH, F.R.C.S. Eng.
Lee, S.E., Feb. 13th, 1905.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Ancoats Hospital.

A CASE of death from blood poisoning occurred at the Ancoats Hospital on Jan. 18th and at the inquest some strictures were passed on the system in vogue for treating slight cases of accident. A young married mill-hand on Dec. 23rd scratched her hand in the mill. Next day she had pain and was taken to the hospital where she was attended to by a nurse and told to come next morning. However, she eventually died with all the symptoms of general blood poisoning on Jan. 18th. The resident house physician, Dr. F. G. Hack, said it was the custom for the nurses to treat trivial cases of accident without consulting the medical officer. The two medical men present could not deal with all the cases. They had 100 beds upstairs to look after. A verdict of "Accidental death" was returned. The jury did not attach blame to anyone but expressed the opinion that every accident should be seen by a qualified medical man. Dr. Hack promised to convey the recommendation to the governing body. In this case the pain in the arm and other symptoms might have led a medical man to take a more serious view of the matter than that taken by the nurse and the confidence of the public generally would no doubt be lowered if it came to be understood that accidents apparently slight but susceptible of fatal developments would probably be seen by a nurse only.

Degrees in Dentistry.

At a meeting of the court of the University of Manchester held on Jan. 18th Professor W. Stirling, in accordance with the recommendation of the board of faculty, moved the adoption of proposed ordinances for degrees and diplomas in dentistry. The Manchester Dental School was founded in 1885 and there are now about 40 students. These students pass the same matriculation as others and before they obtain a licence to practise have to study for four years. Special attention has to be given to dental anatomy and physiology, human and comparative. They go through the same attendance on surgery and pathology as required for the medical students and must have a year's attendance at a general hospital for clinical surgery. The student has to learn the mechanical part of his art at a dental hospital. It was proposed to institute degrees in dentistry of Bachelor of Dental Surgery and Master of Dental Surgery. In this Manchester is not alone, Trinity College, Dublin, and the University of Birmingham already giving dental degrees while Liverpool proposes to do so. The motion, which was seconded by Dr. J. Dreschfeld, was carried and it was resolved that the adoption of the ordinances should be communicated to the Universities of Liverpool and Leeds and to the General Medical Council.

Manchester Royal Infirmary.

The annual meeting of the trustees of the Manchester Royal Infirmary was held on Feb. 10th. Mr. Cobbett, the chairman of the board of management, gave some interesting information as to the progress being made towards the erection of the new infirmary at Stanley-grove. The ground was cleared, sewerage and drainage work had been executed, so that now the surface was ready for the commencement of the laying of the foundations. There is still some anxiety among a section of the supporters of the infirmary as to the central receiving house. It was decided some time since that there should be no beds but the fear seems to be that so much may be expended at Stanley-grove that there may be no funds available for the receiving house even without beds. The chairman was able, however, to remove that impression. Two gentlemen resigned the membership of the board because they could not share in the financial responsibility for the scheme which they consider too costly. One of them, moreover, gave as an additional reason a supposed change in the character of the institution, that "it will become much more a teaching hospital instead of the primary one for the treatment of the sick poor." (The construction here seems to present some difficulty.) "Placed there the professional influence will increase and the lay share in the management must decrease," a state of things to which he objects. It seems a curious idea, and one that could only occur to a layman, that there is any antagonism between the treatment of a patient where it is carried out under the quick, intelligent eyes of students of medicine and that given where there are none to observe and none to criticise—the only difference at all likely to occur being, perhaps, that in the former case it will be more thorough and more carefully carried out than in the latter. If this change is objected to the strong man would retain his post in order that he could oppose the change and not retire on the mere rumour that such a change may be impending. Manchester is a great medical centre and the teaching and education of the next generation of practitioners is surely as important a work in relation to the welfare of the people as any that can occupy the best energies of the wisest and most benevolent among us. There is plenty of room for the coöperation of lay and professional helpers. For many years past they have worked cordially together, to the great advantage of the community, and there is no reason to fear that their relations will be less useful and agreeable in the future.

The Hospital for Skin Diseases.

The new hospital in Quay-street, adjoining the old one, is approaching completion and it is expected that the whole scheme may be completed next year. An appeal for funds has brought in nearly £31,000 but £5000 more are required. Of the 57,159 attendances during the year 22,665 were made by "light" patients. Dr. R. B. Wild said the results of the special "light" treatment were highly satisfactory. The x rays, the Finsen, and the Finsen-Reyn lamps had been chiefly used. Radium had not fulfilled the high expectations of a year ago but this was thought to be "largely due to the fact that the amount of radium available was sufficient to treat only such small areas of disease that they could be treated more effectively by other methods."

Early Marriages in Burnley.

Burnley is, as you are aware, one of the Lancashire towns notorious for its high infantile death-rate. In 1903 it was at the rate of 269 per 1000. One of the ministers of the town has very usefully occupied one Sunday in the month with a series of addresses on "Burnley Black Spots" and he recently spoke on the infantile death-rate and its causes. Speaking generally, he attributed it to "drink, bad housing, early marriages, and the factory system, under which large numbers of married women in the very early morning take out their children to be nursed by women who had also their neighbours' children to look after and whose one idea was to make the babies sleep." The one point specially brought out is the unusual prevalence of early marriage as compared with some of the other Lancashire towns. Oldham has 20 persons married under 18 years of age, while Burnley has 38, and 72 under 19 years of age as against 111 at Burnley. Bolton and Blackburn have 31 and 26 respectively married under 18 years of age. The figures apply in the main to the factory or mill workers and when we consider the poor, and in many cases the miserably poor, physique of this class in the manufacturing towns, as illustrated among other things by the high percentage of rejections of would-be recruits and remember that so many of them, boys and girls, marry before attaining to the full height of their puny development, it is not to be wondered at that their children are feeble and degenerate and little able to withstand the adverse influences surrounding them from the moment they draw their first breath. Nor is it to be wondered at that this widespread enfeeblement of a large proportion of the population should cause anxiety and foreboding for the future.

The Midwives Act.

The Manchester corporation, in view of the fact that the Midwives Act will come into operation on April 1st, has taken steps for the carrying out of the obligations to be imposed on it. In August last it appointed a special committee—the midwives supervising committee—which was to receive the delegated powers of the council as the local supervising authority. It consists of 12 members of the council and four co-opted members, Dr. Arnold W. W. Lea, Dr. Ernest Annacker, Mr. F. C. Scotson, and Dr. Margaret S. Bell. The first duty of the committee was to appoint a qualified medical practitioner to act under the supervision of the medical officer of health as the "executive officer" under the Act. There were 40 applicants for the post, which carries a salary of £250, and they included six lady doctors. The committee recommended the appointment of Dr. Margaret Merry Smith. She will be required to devote the whole of her time to the work, to visit midwives "both systematically and irregularly," and to see that their homes are in a sanitary condition, to examine their cases or bags of instruments, to ascertain that their case-books are properly kept, and that they understand the use of antiseptics, and also that they are "suitably provided in washable dresses." She will also be required to visit the cases attended by the midwives to satisfy herself that the requisite procedures are carried out, that there is strict cleanliness in all things, and that "suitable provision is made for the dieting both of mother and child." In cases of great poverty is the corporation going to feed the mother and child or will that be left to the guardians? She will also take charge of the notifications of deaths and stillbirths and report to the local authority any case of negligence, malpractice, or misconduct. The local authority may, after investigation, report to the Central Board. The local authority may, if it should seem necessary, suspend a midwife to prevent the spread of infection. The lady appointed will have to lead a "strenuous life."

Feb. 14th.

LEEDS.

(FROM OUR OWN CORRESPONDENT.)

The Court Dinner of the University of Leeds.

UNDER the chairmanship of the Pro-Chancellor, Mr. A. G. Lupton, the first Court dinner of the University was held on Feb. 6th. The guests numbered about 110 and included the Lord Mayor of Leeds, the Vice Chancellor, Sir Francis Powell, Mr. Rowland Barran, M.P., and many representatives of local authorities and of educational bodies. It was well attended by the professorial staff and by other members of the teaching body. The toast of "The University" was proposed by Mr. Alfred Moseley, C.M.G., who was the guest of the evening. He gave his experiences in Germany and in the United States and his speech was a strong claim for due recognition being given by all who have the welfare of the empire at heart to the necessity of a sound scientific, technical, and business training of university standard being accessible to all who were likely to be able to profit by it. In his reply the Pro-Chancellor stated that the assets of the University were worth £300,000 and that there were upwards of 800 day students and 300 evening students. He acknowledged the generosity of the Clothworkers Company and expressed the hope that the imagination of wealthy men might be fired and that the University might benefit by their contributions. The Mayor of Bradford in an eloquent speech appealed to the authorities of the University to develop the highest ideals of a university in arts, science, law, and medicine, and Sir Francis Powell spoke in favour of the old classical studies.

The Finance of the General Infirmary.

Under the will of the late Mr. Christopher Charles Weatherill of Leeds this institution will receive a very welcome and handsome addition to its funds. Mr. Weatherill, who died in 1902, directed that his household furniture, plate, books, &c., should be given to his sister and directed his trustees to pay her an annuity of £300 for life. His real estate and the residue of his personal estate was given to his trustees upon trust to accumulate the whole of the income of the estate at compound interest until the death of his sister when the principal and accumulations were to be handed to the treasurer of the Leeds General Infirmary. That lady died on Feb. 10th and when the death and legacy duties are paid the sum at the disposal of the infirmary will be something between £116,000 and £117,000. The conditions stipulated for by the testator are as follows—viz., that a ward be founded and sufficiently equipped and endowed in the infirmary for accident cases, to be called the "Weatherill Accident Ward"; that a white marble monument of the testator with a suitable inscription be erected in the ward, and that the treasurer of the infirmary cause a copy of the will to be placed once every year in a conspicuous position so that everyone entering the infirmary may see it. Subject to these conditions the surplus is to be applied to the general surgical purposes of the infirmary. The financial condition of the infirmary has for some years been matter of increasing anxiety to the board of management. Three years ago the treasurer had to announce that the annual expenditure exceeded the income by some thousands of pounds, and it was felt that unless an increase of income could be secured the work of the greatest of the Leeds charities would have to be curtailed. As the result of a very special effort initiated and energetically carried on by the treasurer, Mr. Charles Lupton, the annual expenses have been met and the work has not had to be curtailed. The expenditure for 1903 was £32,700, as against £30,500 for 1902, while for 1904 the expenditure cannot fall short of £34,000. This expenditure is bound to increase if the high standard of work of the infirmary is to be maintained. The maintenance of the new Arthington Hospital at Cookridge, which is really a part of the infirmary and under the management of the board, will involve an additional expenditure of £2000 per annum. For some years it has been felt by the staff that the institution of a properly equipped clinical laboratory is essential, and the board are giving this, as it always does the suggestions of the staff, its careful consideration.

The Leeds Association for the Prevention and Cure of Tuberculosis.

This association has issued its fifth annual report. For some time after the institution of the association the work was experimentally carried on near Otley, in Wharfedale, some ten miles from Leeds. The next step was the fitting up of Gateforth Hall as a sanatorium. Gateforth Hall is the property of the Leeds corporation, is situated near Selby, and is let at a reasonable rent to the association. The accommodation here has now been raised and 30 patients can be treated. There are extensive grounds and gardens on the estate and in many respects the place is well adapted for the purposes of a sanatorium. The number of patients treated during 1904 was 101 and the average number of days spent by each patient in the sanatorium was 101½. The results of treatment have been distinctly encouraging. At the central offices of the association in Leeds applicants for admission are examined by the honorary officers. The number of applicants has been uniformly much in excess of the accommodation at Gateforth and naturally the cases most suitable for sanatorium treatment have been selected. In this way the necessity of instituting a home or hospital for the more acute class of cases or for cases in which it was doubtful whether sanatorium treatment would be successful became apparent, and this year the society is able to announce that it has secured Armley House and has fitted it up as a hospital which will accommodate 27 patients of this class and which is admirably adapted for the purpose.

Holidays for Poor Children.

Following the example of other centres Leeds has started a poor childrens' holiday camp. The first annual report dealt with the work at Hest Bank, Morecambe. Though the work was not begun till July 130 boys and 130 girls had been kept for various times in the camp. The health of the children had been good. The cost per child of from eight to 14 years of age had been 5*s.* 3*d.* per week—3*s.* 11*d.* for food and 1*s.* 4*d.* for railway fare. The diet had been generous and in many cases the children had gained six pounds in weight. For the next five years the camp is to be held at Silverdale, the rent of the site having been generously promised by Mr. and Mrs. Arthur Briggs, who during Mr. Briggs's mayoralty did so much for the initiation of the scheme. One of the buildings of the Bradford exhibition has been purchased and erected at a total cost of £374 and it is hoped that the forthcoming season may be started with a few pounds in hand.

Feb. 14th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Irish Medical Association and the Local Government Board.

THE opening stage of the appeal by the Irish Medical Association against the action of the Local Government Board in abolishing a dispensary district in the county of Louth was reported in THE LANCET of Feb. 4th, p. 328. The Lord Chancellor has since delivered the judgment of the Court of Appeal, dismissing with costs the appeal of the Irish Medical Association and upholding the action of the Local Government Board.

Royal College of Surgeons in Ireland.

It is publicly announced that owing to the illness of His Excellency the Lord Lieutenant the conferring of the Honorary Fellowship of the Royal College of Surgeons in Ireland on the Provost of Trinity College and the College dinner for which invitations were issued for Feb. 11th have been postponed until further notice.

Dublin Sanitary Association.

At a meeting of the Dublin Sanitary Association held on Feb. 9th a letter from the secretary of the public health committee of the corporation was read stating that the by-laws to regulate street trading by children in Dublin, under the provisions of the Employment of Children Act, 1903, as approved by His Excellency the Lord Lieutenant, are being printed and that badges are being prepared to be worn by the children licensed to trade in the streets of the city.

British Medical Association.

The annual meeting of the Leinster (formerly Dublin) branch of the British Medical Association will be held on Saturday, Feb. 25th, at 4.30 P.M., in the hall of the Royal College of Physicians, Kildare-street, when Sir Thomas Myles, president-elect, will deliver the address. The annual dinner of the branch will take place in the College hall at 7.30 P.M. on the same day.

Honour for Sir Francis Cruise.

Sir Francis R. Cruise, M.D. Dub., D.L., Honorary Physician-in-Ordinary to His Majesty in Ireland, has received a brief from the Pope appointing him a Knight of the Order of St. Gregory the Great, together with the star or decoration of that order.

Dispensary Medical Officers' Salaries.

A special committee of the Coleraine guardians having conferred with the medical officers of the union as to the scale of salaries recommends the following plan to be adopted. That the minimum salary of each dispensary medical officer in the union, as well as that of the workhouse medical officer, be £100 a year, increasing by £10 every five years to a maximum of £150. A statement of the medical officer points out that a penny in the £1 in all Ireland amounts to £62,000 and that the salaries of all the dispensary medical officers amount to £88,000, half of which is recouped by the Government. An average ratepayer of £24 valuation pays a little over 1*s.* to the dispensary medical officers, so a halfpenny in the £1 added would give all that the medical officers ask. The matter is to be considered at a future special meeting of the board.

The Public Bodies Order.

The Local Government Board has issued an Order for the guidance of public bodies in Ireland which is being strongly and adversely criticised on the grounds that it increases clerical work and expense of maintenance without effecting any improvements which might compensate for these disadvantages. For instance, in reference to asylums this Order prescribes new forms relating to the audit of asylum accounts which will necessitate more officials and will interfere with the smooth and economical working of such institutions. The duty of the Local Government Board is clearly to see that local bodies transact their business honestly and that they fulfil the law but it is absurd to make vexatious regulations which serve no good object but increase the expense of local bodies. At the ordinary meeting of the Belfast asylum committee on Feb. 13th a motion was unanimously carried protesting against the adoption of such an Order on the ground among others that it contains provisions which exceed the statutory powers of the Local Government Board. Other local bodies in Ireland are taking similar action.

A Health Lecture for the People.

A lecture fully illustrated by limelight views was delivered in the Exhibition Hall, Belfast, on Feb. 14th, by Dr. Henry O'Neill, editor of the *Belfast Health Journal*, on the Health of Belfast. A collection was made in aid of the Belfast Royal Victoria Hospital.

Feb. 14th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Brewer's Yeast in the Treatment of Typhoid Fever.

AT a meeting of the Medico-Chirurgical Society held on Jan. 23rd M. Hirtzmann gave details of three severe cases of typhoid fever occurring in adults. The symptoms included dryness of the tongue, diarrhœa, and other conditions usually found in typhoid fever; the temperature rose to, and remained at, 40° C. (104° F.) for some time. In addition to small amounts of sulphate of quinine he gave to all three patients 60 grammes (two ounces) of brewer's yeast daily in three doses. This treatment was commenced about the seventh day of the illness. After the taking of the yeast the temperature fell to 38° C., not subsequently rising above 39°; the gastro-intestinal symptoms improved, the tongue was no longer dry and coated, the diarrhœa disappeared, and the pyrexial stage terminated about the twenty-first day. M. Hirtzmann believed that the yeast acted as an antiseptic. He employed either Karcher's or Grueber's fresh yeast, the latter being preferable as it was almost liquid. In those cases the typhoid fever was unquestionably water-borne, for the well supplying the house of one of the patients had been evidently contaminated by fæcal matter from a house which stood at a higher level and in which there had been some time previously a case of typhoid fever.

Respiratory Exercises and Re-education in the Treatment of Convalescents.

At a recent meeting of the Société Médicale des Hôpitaux M. Siredey and M. Rosenthal contributed a paper on Respiratory Exercises and Re-education in the Treatment of Convalescents. They said that respiratory insufficiency was one of the causes of the general debility which showed itself after an acute illness. It was easily recognised by the following symptoms which the patient presented—namely, nasal insufficiency, shown by inability to breathe 20 times through both nostrils; thoracic insufficiency, shown by absence or impairment of the movements of the thorax; and diaphragmatic insufficiency, shown by immobility or recession of the abdomen during inspiration, a condition met with in pseudo-pleurisy of the bases of the lungs. Respiratory re-education under medical supervision was, in their opinion, the specific treatment for respiratory insufficiency. In the case of convalescents it constantly produced a progressive threefold effect—namely, expansion of the thorax, diuresis, and increase of weight. It promoted in a marked degree the recuperation of the vital functions which followed acute illnesses and the general health of the patients improved rapidly. It ought to be combined with other forms of treatment and the action of the latter was enhanced by it. Although of great power it did not require for its application any special institution or any special apparatus. The system could be practised anywhere, either in a hospital or in the poorest dwelling. It needed nothing more on the part of the patient than the absence of any mechanical obstacle to the passage of air through the rhinopharyngeal tract, and nothing more on the part of the medical man than a willing mind and a qualification which was indispensable though too much neglected—namely, a knowledge of the fundamental laws of human physiology.

Poisonous Cream Cakes.

M. Metchnikoff, the deputy director of the Pasteur Institute, has just been taking part in an interesting inquiry. For some months past he has been receiving almost daily samples of cream cakes from the same batch as those which had given rise to symptoms of poisoning in those persons who had eaten them. M. Girard of the Municipal Laboratory had also investigated the cakes. The Society of Confectioners and Bakers was aware of these researches and its members, when they knew that results had been obtained, convened a meeting at which Dr. Metchnikoff gave an interesting discourse. The cause of all the mischief, he said, was the white of the egg which contained microbes. It is not clear why the white of certain eggs contains microbes but the fact is certain that some hens do lay eggs the whites of which contain microbes. Even freshly laid eggs when cultivated in a cultivator give cultures. This being so the method in which the cream is prepared for the cakes is eminently calculated to develop the microbes. The white of egg slightly warmed is sprinkled with a "cream" which itself is at a temperature of 80° C., one far too low to have any destructive effect on the germs. This "cream" being made of gelatin, sugar, and milk offers an ideal culture medium when the mixture is warmed. This explains why white of egg, even when it does contain germs, gives rise to no symptom of poisoning when it is consumed in the ordinary way without the admixture of "cream." The following method is suggested to avoid future risks. Before sprinkling the white of egg with the "cream" it should be coagulated in boiling sugar which will certainly destroy the germs.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

The Prevention of Yellow Fever in Cuba.

THE American Public Health Association met in Havana on Jan. 10th and the principal feature of the introductory proceedings was the address of the President, Dr. Carlos Finlay, chief of the Cuban Health Department. He highly eulogised the labours of American experts to whom, he said, was due the banishment of yellow fever from Cuba. The American Commission, under the leadership of the late Major Reed, had decisively established the true etiology of yellow fever. Dr. Finlay also praised the work of Major Gorgas, chief health officer under General Wood, who, adopting the findings of the commission, succeeded within seven months in ridding Havana of the inveterate enemy. Regarding the two cases of yellow fever which occurred in Santiago Province, Dr. Finlay said it was presumed that they were transmitted by mosquitoes from a quarantined ship. There can be no doubt that the American medical men did a great work in ridding Cuba of yellow fever and are entitled to all the praise bestowed upon them by Dr. Finlay. It would, however, seem from recent reports that since the Cubans themselves have taken over the government of the island sanitary affairs therein have decidedly retrograded. It is therefore needful that the American Government, for the sake of the inhabitants of Cuba, as well as in the interests of the American people at large, should strongly advise, and if necessary bring pressure to bear on, the Cuban authorities in order that the sanitary conditions of Cuba should not be allowed to lapse into their former unsatisfactory state through neglect.

Alleged Swindle by Physicians.

Two physicians were arrested in New York recently charged with engineering a radium cure swindle. The case against them was brought by the New York County Medical Society through its attorney, Mr. Champe S. Andrews. The complainant, a carpenter, stated that the physicians had obtained from him $10,000 (£2000), the amount of his savings of years. The carpenter had been informed by the medical examiners of an insurance company that he had a slight tendency to Bright's disease and went to the defendants for treatment. He was told by them that he was suffering from Bright's disease in its worst form and that his only chance of recovery lay in his being treated by means of radium. He was further told that owing to the great cost of radium the treatment would be very expensive. Acting upon his fears the defendants managed to extort from the plaintiff the sum above mentioned. The New York County Medical Society's agents heard of the matter and initiated an investigation, with the result that some of the so-called radium was obtained and subjected to a searching analysis when it was found that the composition contained no trace whatever of radium, but, as a matter of fact, consisted of gentian, iron, and a few simple drugs ordinarily used in a tonic preparation.

The Adulteration of Whisky

Dr. H. W. Wiley, chief of the United States Bureau of Chemistry, has recently stated that he believes at least 85 per cent. of the whisky sold over the bars in the United States is not "straight" whisky. He states that it is a compound, made of neutral spirit, or alcohol, artificially coloured, often flavoured with artificial essences and sometimes mixed with more or less "straight" whisky to give flavour. The remarks of Dr. Wiley on the adulteration of food and whisky have given rise to much heart-searching and the liquor dealers have been endeavouring to minimise as far as possible the effect of his statements. There can be no doubt, however, that adulteration is conducted on a wholesale scale in the United States and it is not unlikely that the Federal and States Governments may take cognisance of the matter and endeavour to check the evil by means of legislation.

Tuberculosis and Alcohol.

A controversy has been going on in the lay press of New York with regard to the effect of alcohol upon consumptives. Dr. Wiley has recently "stirred a hornet's nest" by making public his opinion that alcohol is beneficial in consumption as well as in certain other diseases. Dr. Knopf, the well-known New York authority on tuberculosis, has stoutly combated these views and declares that in any stage or form of pulmonary tuberculosis large quantities of alcohol are contra-indicated. These views are in direct opposition to those held by Dr. Arthur C. Latham who, writing on the subject in the *Practitioner* for January, declares that when solid food cannot be taken by consumptives alcohol is our sheet anchor and in another part of the same article says that "nothing but good results from the administration of large quantities of alcohol when fever is present so long as the pulse is becoming slower, the appetite better, the skin and tongue moister, and the patient quieter." Opinions diverge greatly as to the position of alcohol as a nutritive agent. In America probably the medical profession is almost equally divided on the question.

Feb. 6th.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

A Case of "Sati" in Behar.

THE desire for the barbaric custom of "Sati" seems to still linger in the Hindu mind. A recent case in Behar was attended by an enormous and sympathising crowd and the village watchman refused to lay information with the police. A Brahmin died and the body was laid on the pyre. The widow, having bathed in the small river close by and adorned herself as for her marriage, took her seat on the [illegible] to have stood up, then turned towards the setting sun and immediately fell back, apparently overcome by the rapidly increasing flames. During this time the crowd were shouting their incantations, there were beating of drums and clanging of cymbals, and probably little or nothing was heard of any cries from the terrible pyre. Fortunately the son and his accomplices have had severe punishment administered to them and this horrible offence is not likely to be repeated.

Lady Ampthill Nurses' Institute.

This nursing institute was started in Madras last July but the staff of nurses has only recently been completed. Two of the nurses have come out from England, the others having been trained in India. Good work has already been done and the want of a trained nurse so long felt in Madras has to a great extent been remedied. This want is greatly experienced in nearly all parts of India except in the cities of Calcutta and Bombay and the establishment of other institutes and nursing associations is under consideration.

The Increasing Plague Mortality.

The mortality from plague throughout India is rapidly increasing. Last week there were 25,719 deaths, as compared with 24,385 for the previous seven days and 22,645 recorded for the last week of the past year. The United Provinces returned 11,777 deaths, the Punjab 5569, Bengal 3318, the Bombay districts 2886, the Central Provinces 444, Hyderabad State 399, Rajputana 352, Madras Province 341, Bombay city 192, and Calcutta 33. Since these figures were published plague has broken out in a fishing village on the outskirts of Madras city. The village has been burnt and the patients and "contacts" have been segregated. Dead rats discovered have been found to be swarming with plague bacilli. The Mauritius emigration depôt adjoining with about 500 emigrants has been declared plague-infected and a special quarantine depôt has been established. Another village has been found infected but no further cases have occurred amongst those isolated. This looks as if Madras city, which has escaped so long, will at last be stricken with the disease. The recrudescence in Bombay City and Calcutta is developing and the former is also suffering from a severe outbreak of small-pox. During the past week the whole of Northern India has experienced severe cold and as the greatest mortality is now occurring in those parts we shall be able to see if the course of the disease is in any way modified.

Jan. 28th.

Medical News.

TRINITY COLLEGE, *DUBLIN*.—At examinations held in Hilary term the following candidates were successful:—

FINAL EXAMINATION.

Section A.—Gustav W. Thompson, William Hutchinson, Richard A. Connell, Malcolm K. Acheson, Archibald L. Robinson, Theodore C. Somerville, Charles G. Sherlock, Henry D. Woodroffe, Wilfred L. Hogan, Langford V. Hunt, Herbert J. Wright, and Francis O'B. Kennedy.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. Karl Kaiserling, *privat-docent* of Pathological Anatomy, and Dr. Heinrich Wolpert, *privat-docent* of Hygiene, have been granted the title of Professor.—*Munich:* Dr. Robert Gaupp has been recognised as *privat-docent* of Psychiatry.—*Naples:* Dr. Ugo Benenati and Dr. Giovanni Castronuovo have been recognised as *privat-docenten* of Internal Pathology.—*Prague* [illegible] Eduard Pietrzikowski, *privat* [illegible] dolf Fischl and Dr. Raudnitz, [illegible] have all been granted the [illegible] Dr. Wilhelm Schlesinger has been recognised as *privat-docent* of Internal Medicine.

THE LONDON, ABERDEEN, BANFF, AND KINCARDINE ASSOCIATION.—The annual dinner of this association was held on Feb. 10th at the Criterion Restaurant, London. Sir Dyce Duckworth in proposing the principal toast, that of "Scotland," had some rather critical remarks to make upon young Scotland. Allowing that Scotchmen were famous all the world over for *perfervidum ingenium*, he thought it a question whether the *ingenium* was so perfervid as in former times. The facilities of communication had become so numerous, luxury had grown to such an extent, and there was so much Carnegie-spoon-feeding north of the Tweed that doubts had arisen as to whether the earnestness and assiduity of the rising generation in Scotland were as intense as formerly. Only a few days ago an old undergraduate of the University of Edinburgh told him how he had found in the union of the university students playing whist in one room and billiards being played in another at 3 o'clock in the afternoon in the middle of the winter session. As an old student of the university he of course remembered billiards and whist being played there and he had no objection to whist and billiards in their proper place, but he doubted the advisability of students playing cards and billiards at 3 o'clock in the afternoon and he hoped that such trivialities would not be permitted to interfere with the work of Scotch students of the present day. He urged students to assume the earnestness and to cultivate the industry which their forefathers possessed. Sir Patrick Manson responded to the toast with a humorous speech. Surgeon-Colonel J. Richardson, in replying to the toast of "The Imperial Forces," proposed by Mr. J. W. Barclay, said that the navy was now so formidable that the mere mention of it got on the nerves of some of our neighbours; in regard to the army it was being forged and when finished it would be a powerful thunderbolt. Amongst those present were Mr. J. Cantlie, Dr. A. M. R. Sinclair, Dr. G. B. Currie, Dr. J. Mitchell Bruce, Dr T. I. Rowell, and Mr. G. Tocher.

RESTRICTIONS ON THE SALE OF PATENT MEDICINES IN VENEZUELA.—The British Foreign Office has received a copy of a decree published in the Venezuelan official gazette of Dec. 15th, 1904, on the subject of the sale of patent medicines. It declares that the sale of patent or secret medicines which are not authorised by the Medical Council, even though approved by foreign faculties, is now prohibited in Venezuela. The decree accordingly provides for the establishment of a commisssion to undertake the examination and classification of such medicines. Manufacturers of foreign patent medicines must submit the products which they wish to import into Venezuela to this commission within four months from the date of publication of the decree. The application must be in the customary legal form and must state the name of the article, the principal ingredient, and the dose to be taken, and should be accompanied by two samples of the article with the same information on the label. Each application—one for each product submitted—will be subject to a fee of 20 bolivars (15*s.* 10*d.*) and the power of attorney must bear a 5-bolivar stamp. Four months from the date of the publication of the decree unauthorised patent medicines will be classified by the Customs in the fifth class of the tariff for a period of two months, during which time they may still be submitted to the commission; this term expired, they will be included in the list of articles prohibited to be imported. Secret or patent medicines subsequently compounded, however, will be examined and classified by the commission in accordance with the regulations.

SALE OF A MEDICAL PRACTICE.—At the Devon Assizes on Feb. 6th and 7th Mr. Ellis Pearson of Bideford sought to recover from Dr. A. Lane damages for fraud in connexion with the sale of the goodwill of a practice at Bideford. The defendant denied fraud and counterclaimed for fees which, he alleged, the plaintiff had received on his behalf. The plaintiff, who employed no solicitor or accountant in connexion with the purchase, admitted that he had received certain of the fees and gave credit for them. Evidence showed that Mr. Pearson purchased from Dr. Lane for £1000 a practice stated to be worth £800 per annum. The practice, however, according to Mr. Pearson, was only worth about £185 a year. After hearing a considerable amount of evidence Mr. Justice Lawrence in summing up said that the only question for the jury to decide was whether there was a substantial practice carried on by the defendant or whether the practice was built up simply and solely for making a good appearance on a rotten foundation for the purpose of selling it. The jury found that the practice was built up for sale and assessed the damages at £200. It was stated that the plaintiff had paid £57 into court, a sum realised by the collection of outstanding debts, and judgment was given for Mr. Pearson for £143.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.—A quarterly meeting of the Royal College of Physicians of Edinburgh was held on Feb. 7th, Dr. J. Playfair (the President) being in the chair. Dr. Alexander Goodall was introduced and took his seat as a Fellow of the College. Mr. David Duncan Main, M.R.C.P. Edin., L.R.C.S. Edin., Shanghai, China, was admitted by ballot to the Fellowship of the College. Mr. Patrick Hehir, L.R.C.P. Edin., F.R.C.S. Edin., Manipur, Assam, was admitted by ballot to the Membership of the College after examination. The registrar reported that since the last quarterly meeting 44 persons had obtained the Licence of the College by examination.

THE STUDENTS' UNION, ST. BARTHOLOMEW'S HOSPITAL.—The committee of the Students' Union of St. Bartholomew's Hospital has decided to hold annually one or more smoking concerts to promote the social intercourse amongst all St. Bartholomew's men. The proceeds will go to the funds of the union. The second smoking concert will be held on Monday, Feb. 27th, in the Grand Hall of the Criterion, at 8.15 P.M. Mr. Anthony Bowlby, F.R.C.S., C.M.G., will be in the chair. Tickets, price 1*s.* 6*d.* each, can be obtained from the secretaries at the hospital, Mr. W. G. Loughborough and Mr. H. J. Gauvain.

CENTRAL MIDWIVES BOARD.—The members of the Central Midwives Board met on Feb. 9th at 6, Suffolk-street, Pall Mall, W., Dr. F. H. Champneys being in the chair. The report of the standing committee concerning the applications for recognition as teachers of midwifery and the applications for approval of certain institutions as training schools for midwives was submitted to the Board. Mr. E. Parker Young expressed his opinion that applications for approval as training schools should not be postponed from meeting to meeting but that the Board should come to some conclusion in regard to each case. Before the report of the standing committee was formally received by the Board and adopted Sir William J. Sinclair delivered his judgment on the Board and its methods in the following terms:—"As a ground for declining to discuss in detail the applications before the Board I desire to state my opinion that the Board has recognised such unsatisfactory applicants as teachers of midwifery and has approved such unsuitable institutions as midwifery training schools that I do not see on what principle I can now object to any applicant for recognition as a teacher or to any institution as a training school. I can only look forward to the Board continuing its present policy so that an unanswerable case will soon be made out for reconstitution of the Board by an amendment of the Act." The Board decided that Poor-law institutions before being approved as training schools for midwives should be subjected to investigation and report and on the suggestion of Sir William Sinclair directed that when considering any application from a workhouse infirmary to be recognised as a training school for midwives a report should be asked for from the chief medical officer and the local supervising authority concerned should be requested to inspect and to report to the Central Midwives Board on the institution.

TWENTY-THIRD ANNIVERSARY DINNER OF THE WEST LONDON MEDICO-CHIRURGICAL SOCIETY. — The members and friends of the West London Medico-Chirurgical Society held the twenty-third anniversary dinner on Feb. 8th at the Wharncliffe Rooms, Hotel Great Central, the chair being occupied by the President of the society, Mr. C. M. Tuke. The President having duly proposed the toasts of "The King" and "The Queen and other Members of the Royal Family," called upon Mr. Alban H. G. Doran to propose the toast of "The Imperial Forces." Mr. Doran in a well-informed speech referred in detail to the changes in the navy which could only result in efficiency. This toast was replied to by the Director-General of the Medical Department of the Royal Navy who made a special reference to the new system to be followed in the naval manœuvres. He commented on the number of famous medical men who had served in the navy, mentioning the names of Professor Huxley and Sir Spencer Wells. Lieutenant-Colonel E. M. Wilson, R.A.M.C., speaking for the sister service, described how keen the men of the Army Medical Service were in the prosecution of their work. The Royal Army Medical Corps was picking out good men in medicine, surgery, and special branches of work and giving opportunities for study and practice. He observed that many of the officers of the Royal Army Medical Corps when they took their study leave came to the West London Hospital where they derived great benefit. The toast of "The Kindred Societies and Guests" was proposed by Dr. Seymour Taylor and responded to by Sir William S. Church and Mr. J. Langton. The toast of "The Society and its President" was proposed by Dr. G. H. Savage who complimented those present on the large number at the dinner, amounting to over 120. After the President had made a suitable reply conversation became general and the company separated at a late hour. Great praise was accorded to Dr. A. Elliot, the senior secretary of the society, for his efforts which resulted in securing a record attendance at the dinner.

DINNER TO SIR ISAMBARD OWEN.—On Saturday last, Feb. 11th, a highly successful and pleasant dinner was given at the Imperial Restaurant, Regent-street, W., to Sir Isambard Owen, principal of the Durham College of Science, by a large number of his friends, colleagues, and late pupils at St. George's Hospital. Before his appointment as principal at Durham Sir Isambard Owen was for 23 years upon the medical staff of St. George's Hospital, and during a large part of that time he filled, and filled with energy and devotion, the delicate post of dean of the school. During the dinner opportunity was taken to present the guest of the evening with a silver tea service as a wedding gift, Sir Isambard Owen's impending marriage having been announced.

UNIVERSITY OF CAMBRIDGE.—The Special Board for Medicine has added to the list of recognised provincial hospitals at which study for the degrees of M.B. and B.C. may be pursued the United Hospitals Clinical School of Liverpool.—The third examination (Part II.) for medical and surgical degrees will begin on May 2nd. The names of candidates should be sent to the registrar by April 17th.—The graces for the establishment of the Huddersfield Lectureship in special pathology passed the Senate on Feb. 16th. The appointment will be made this term.—Sir M. Foster has been appointed an elector to the chair of Physiology and Professor W. F. R. Weldon an elector to the chair of Zoology and Comparative Anatomy.—Dr. D. MacAlister, president of the General Medical Council, having resigned the office of secretary to the Special Board for Medicine, which he has occupied for over 20 years, Dr. Laurence Humphry has been appointed secretary in his place.

PHYSICAL VOICE TRAINING. — A meeting in furtherance of the objects of the Physical Voice Training Society was held at the Medical Society's Rooms, Chandos-street, Cavendish-square, London, W., on Feb. 1st. The Bishop of Bristol presided. The following resolutions passed at the meeting of the society held at Oxford last August were read:—

> That the subject of voice training being of such vital importance for public speakers great attention should be paid to it in education, especially at the public schools and universities, in accordance with the memorial on voice training of the British Medical Association.

(The memorial referred to was issued from the offices of the association on Nov. 18th, 1893, and was the outcome of a suggestion of the section of laryngology at the annual meeting of the association held at Nottingham in the previous year.) The second resolution passed at Oxford was as follows:—

> That the Physical Voice Training Society founded by the originators of the "Memorial on Voice Training" issued by the British Medical Association on Nov. 18th, 1893, is deserving of further support from the medical profession in general and the laryngologists in particular.

The Chairman said that the object of their meeting was to consider what steps should be taken to give effect to those resolutions. He was strongly of the opinion that there was great need of careful attention to the best methods of voice-producing not only for the clergy but for all engaged in public speaking; he considered that the services in churches could be improved by a proper course of voice training being undergone by those who conduct them; further, that the usefulness in after life of many educated in the universities and colleges was in some measure lost through their not being effective on the platform. In conclusion, he put forward a motion for appointing a committee consisting of clergymen, medical men, and others engaged in educational work to consider and to report upon the means of giving practical effect to the Oxford resolutions.—Dr. W. Jobson Horne, in response to the chairman, also spoke in favour of the motion. He considered that the large number of conflicting methods of voice training was in itself sufficient reason for investigating the matter with a view of putting it on a practical footing; personally he did not advocate or support any one particular method, doubtless there was some good in each and all. The main point with which they were concerned was how they were to arrive at a satisfactory method and what machinery they were to use to give practical effect to it. It was now some years since the society was founded and the desirability of reconstituting it would doubtlessly receive the attention of the committee which they were about to appoint; he was quite prepared to accept the statement that as many voices had been ruined as had been made by voice training and that made the responsibility of such a society. Dr. V. H. Wyatt Wingrave also spoke in support of the motion which being put to the meeting was unanimously agreed to and a small provisional committee was appointed.

DONATIONS AND BEQUESTS.—Under the will of Mr. C. O. Smith of Wolverhampton £1000 are left to the Wolverhampton and District Hospital for Women.—By the death of Mrs. Mary A. Whitfield the sum of more than £100,000 reverts to the [illegible] will of the late Mr. C. C. [illegible] Mr. James Holmes Luckir [illegible] each have been left to the Asylum for Idiots at Earlswood, the National Society for Employing Epileptics, the British Home and Hospital for Incurables at Streatham, St. George's Hospital, King's College Hospital, the London Hospital, St. Mary's Hospital, the Middlesex Hospital, the Hospital for Consumption at Brompton, the Royal Hospital for Incurables at Putney-heath, and the National Hospital for the Paralysed and Epileptic; £1000 each to Charing Cross Hospital, Guy's Hospital, the Metropolitan Hospital, the London Free Hospital, the Seamen's Hospital Society, the Westminster Hospital, University College Hospital, the East London Hospital at Shadwell, the City of London Hospital for Diseases of the Chest, the Evelina Hospital for Sick Children, the Hospital for Sick Children at Great Ormond-street, the Victoria Hospital for Children, the Hospital for Women, Soho-square, the Samaritan Free Hospital, the Cancer Hospital at Brompton, the Female Lock Hospital, Harrow-road, the Royal London Ophthalmic Hospital, Moorfields, the Bexhill Convalescent Home, All Saints' Convalescent Home at Eastbourne, the Royal Sea Bathing Infirmary, and the Indigent Blind Asylum; and £500 each to the North London Hospital for Consumption at Hampstead, the Royal Hospital for Diseases of the Chest, City-road, the Royal National Hospital at Ventnor, and St. Andrew's Home at Folkestone.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The New Session.

IT is very difficult to say what will be the course of the new session which the KING opened on Tuesday. Members have no better information on the subject than the man in the street; all are agreed, however, that anything may happen at any moment. During the last ten years no such state of uncertainty has existed. In the days immediately before the fall of the Rosebery Government in 1895 matters were almost as unsettled and unsettling but the complexity of the situation was as nothing compared with the situation to-day. In a week's time we shall have more data to go upon in estimating the chances.

Legislation.

The forecast of legislation contained in the King's speech reveals no unexpected proposals. It is practically an official confirmation of the various rumours that have been circulating for weeks. None of the proposals mentioned would directly affect the medical profession. For anything of that sort we shall look to the pigeon-holes of the departments. In one of these pigeon-holes we know there is to be found the Lunacy Bill which was introduced by the Government shortly before the close of last session. In due course this measure will doubtless again come before Parliament. As for other legislative proposals concerning the Faculty nothing can be said until the ballot for private Members' Bills takes place.

Sale of Tobacco to Children.

DR. MACNAMARA will ask the Home Secretary on Monday whether his attention has been called to the recommendation of the Physical Deterioration (1904) Committee to the effect that a Bill should be brought before Parliament at an early date having for its object the prohibition of the sale of tobacco and cigarettes to children below a certain age, and whether he is now in a position to say that this recommendation will be acted upon in the present session.

Physical Deterioration.

In the beginning of the week several questions will be addressed to Ministers as to the recommendations of the Committee on Physical Deterioration. The object is to learn whether legislation will be proposed.

needs and painting its name on boards and so on. This is exemplified by the action of the Great Eastern Railway Company which used to paint on each side of every one of its coaches the letters G.E.R., followed by the number, but it may be observed that all the new six-a-side coaches have only the letters G.E., followed by the number."

THE PROGRESSIVE MEDICAL ALLIANCE.

DURING the trial on Feb. 10th at the Central Criminal Court of a man named Holmes for uttering a forged cheque some interesting facts came out about the Progressive Medical Alliance, a quack establishment run by a man calling himself Dr. Talbot Bridgwater, who gave evidence for the defence. Bridgwater said that he carried on business as the Progressive Medical Alliance at 57 and 59, Oxford-street. He was a consulting specialist and had an American diploma. He had been in Australia and had received testimonials from Sir Harry Parkes. In cross-examination he said that he remembered that at various times men employed to deliver his leaflets had been prosecuted and fined for circulating indecent literature. Probably as many as 50 men had been fined. He paid the fines himself as a rule. Last year he had employed a man named Shackell. He knew that Shackell had made a *faux pas*, something in connexion with forging a bill of exchange for £500. He knew Billy Wigram and a man named Robertson. It was exceedingly possible that these two together with a third man had been sentenced at Glasgow to five years' penal servitude for robbing a stockbroker's clerk. He did not provide Wigram with funds for his defence but a man named Haines who had been in his (Bridgwater's) employ, did, he believed, go to Glasgow with money for the defence, which money had been subscribed by some betting men. He came across all sorts of people as patients. Dr. McDonach who was advertised in connexion with his business was Eliza McDonach and one of the women doctors first qualified in London. He did not know where she was now but she was the same as Madame Frickart, having married a man of that name. In the end the jury disagreed but Bridgwater's admissions certainly throw light on the Progressive Medical Alliance. The name of Macdonagh-Frickhart, Eliza Foster, registered as Lic., Lic. Midwif. 1879, K.Q. Coll. Phys. Irel.; M.D. Univ. Zurich, was erased from the Medical Register, May 23rd, 1894, by order of the General Medical Council. Minutes, vol. xxx., 138; xxxi., 59.

THE CASE OF DR. A. D. GRIFFITHS.

To the Editors of THE LANCET.

SIRS,—May I be allowed to announce the following further contributions to the above fund?—Amount previously acknowledged, £37 4s.; Mr. T. Carwardine, £1 1s.; Dr. S. Hamilton, 10s.

I am, Sirs, yours faithfully,
ALEXR. P. FIDDIAN, Treasurer.

23, The Walk, Cardiff, Feb. 14th, 1905.

WANTED—A HOME.

A MEDICAL man residing near London is anxious to discover a home for a man, aged 48 years, who has epileptic fits at long intervals. Between the seizures he is tractable, inoffensive, and fully intelligent. He has a pension for life ot £20 per annum and would willingly accept employment to help to defray the cost of keeping him. His relatives are educated people who cannot now afford to keep him. The inquirer will be glad if any of our readers who can help him will address Mr. Frank Collins, Sproxton, Wanstead.

WHAT THE LANCET HAS NOT SAID.

WE receive material for a weekly article which could justifiably be published under the above title, for no week goes by without our attention being drawn to the wiles of some enterprising advertiser who is asserting that his wares have received a special commendation from us which the facts do not warrant. Our attention has now been called to the fact that a company calling itself the American Tobacco Company of Canada. Limited, is advertising its "Sweet Caporal" cigarettes as "the purest form in which tobacco can be smoked (London LANCET)." We have never said anything of the kind concerning these cigarettes nor have we singled out any cigarette as being composed of the purest tobacco. Some two years ago we made an investigation into the tobaccos employed by a certain number of cigarette manufacturers with the result that we were able to clear Virginian cigarettes from certain accusations of gross adulteration, and we presume that some of the words in our article are held by the American Tobacco Company of Canada to justify its advertisement. Of course, they do nothing of the sort.

SCIENCE ON THE STAGE.

CHEMICAL and physical phenomena have an undoubted attraction for the public and our variety entertainment managers would appear to be vieing with each other just now to exhibit the latest chemical or physical sensation. The magic kettle created considerable interest but it was merely a popular exposition of some of the properties of liquid air. As a completely diametrical set-off to this the public are to be regaled with a demonstration at the London Pavilion of a method for the production of intense heat without the aid of the usual appliances, a blow-pipe even, or the oxyhydrogen flame, or the blast furnace. The method is well known to chemists and engineers and depends upon the intense heat set up by the combustion of a given element at the expense of oxide of iron mixed with it. The combustion is intense and molten iron remains. By this means it is stated that liners or warships may carry an equipment represented in a small heap of powder which will enable them to repair a broken shaft or a propeller. The most striking experiment at the London Pavilion is, perhaps, that in which it is shown that the molten iron produced will fall through cold water and then pierce through an iron plate serving as a bottom to the vessel containing the water. A mixture known as thermit was described in THE LANCET of Feb. 20th, 1904, p. 548, which will give the results mentioned. The combustion of the aluminium at the expense of the ferric oxide is actuated in the case of thermit by means of a mixture of peroxide of barium and metallic aluminium. The heat produced is very intense, the temperature being estimated to be 3000° C. Holes are melted in boiler-plates with the greatest ease, the heat of the oxyhydrogen flame is not equal to thermit, though the heat of the electric arc may be. A mere heap of powder, however, is simplicity itself compared with these appliances

THE WEIR-MITCHELL TREATMENT AND LING'S EXERCISES.

To the Editors of THE LANCET.

SIRS,—Will any of your readers kindly inform me where I can obtain full particulars of treatment of cases of neurasthenia by Weir-Mitchell rest treatment, also by Ling's resistance exercises?

I am, Sirs, yours faithfully,
Feb. 13th, 1905. M.D. BRUX.

*** An account of the Weir-Mitchell rest treatment by the late Dr. Playfair is given in an article on Hysteria in Tuke's "Dictionary of Psychological Medicine."—ED. L.

ARE ENGLISH PERIODICALS CORRUPT?

A GENIAL paper, the *Chicago House Beautiful*, appears to be telling its audience that "The Lancet will praise your table waters ...... possibly all the world understands these statements are worth not more than the 6*d*. a line that they cost." It does not signify to us what stupid lies a paper like the *Chicago House Beautiful* may print concerning us but it is interesting to find how rooted is the belief of the American editor in British corruption. It has not struck the editor of the *Chicago House Beautiful* that, considerations of morality apart, for THE LANCET to receive money in return for making analyses would be a disastrous proceeding, inasmuch as the venality could not remain concealed and the value of the analyses, and indeed of every opinion expressed by the journal, would at once cease to exist. In America, where editorial opinion is in many cases not worth a cent., and where many journals are to all intents owned by their advertisers, the strength of an independent position is so little realised that it becomes unimaginable.

◆

M.B., C.M.—If the dentist in question is on the Dental Register his proceedings are correct but we agree with our correspondent in thinking that many dentists take undue risks in the matter of the administration of anæsthetics. Many general practitioners expressly refuse dental cases.

J. H.—The necessity varies with the size of the room and the facilities for ventilation.

Mr. A. Gavin.—Will our correspondent who addressed a question to us recently from Symington kindly send us his address?

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (20th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. EDITORIAL NOTICES.

IT is most important [illegible] to the Editorial business of [illegible] ldressed *exclusively* "TO THE [illegible] to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. II. of 1904, which was completed with the issue of Dec. 31st, and the Title-page to the Volume, were given in THE LANCET of Jan. 7th.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1904 are now ready. Bound in cloth, gilt lettered, price 18*s.* carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them! Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

The Erasmus Wilson Lectures

ON

PERITONITIS, A BACTERIOLOGICAL STUDY.

Delivered before the Royal College of Surgeons of England on Feb. 20th, 22nd, and 24th, 1905,

By LEONARD S. DUDGEON, M.R.C.P. Lond.,
M.R.C.S. Eng.,
SUPERINTENDENT OF THE CLINICAL LABORATORY AND DEMONSTRATOR OF CLINICAL PATHOLOGY AT ST. THOMAS'S HOSPITAL; GILLSON SCHOLAR IN PATHOLOGY OF THE SOCIETY OF APOTHECARIES; ERASMUS WILSON LECTURER, ROYAL COLLEGE OF SURGEONS OF ENGLAND;

AND

PERCY W. G. SARGENT, M.A., M.B.,
B.C. Cantab., F.R.C.S. Eng.,
RESIDENT ASSISTANT SURGEON AT ST. THOMAS'S HOSPITAL; ERASMUS WILSON LECTURER, ROYAL COLLEGE OF SURGEONS OF ENGLAND.

LECTURE I.

Delivered on Feb. 20th.

Mr. President and Gentlemen,—Our first duty is to thank you for the honour which you have done us in allowing us to bring forward in these lectures the results of our research into the bacteriology of peritonitis. It is impossible, in the time at our disposal, to give more than an outline of the work which we have done and the conclusions at which we have arrived. We have attempted to place the bacteriology of acute peritonitis upon a sound basis, and to deduce from the knowledge thus gained some facts which may serve to guide the surgeon in the treatment of the various diseases which are grouped under the general names of septic or suppurative peritonitis. We hope that the time will come when it will be possible to treat these diseases with some regard to their bacteriology and we hope that our results may be of some assistance in bringing about that desirable end. We have made systematic examinations of the peritoneum in 270 cases operated upon at St. Thomas's Hospital during a period extending over about 16 months. We offer our best thanks to the staff of St. Thomas's Hospital for the interest which they have taken in the work and for the readiness and unfailing courtesy with which they have placed at our disposal the material obtained from their cases.

Technique.

In the large majority of cases the films and cultures were taken by one of us; almost all the remainder were taken under the immediate supervision of one of us whilst operating. This goes far to insure uniformity of method and observation in our series. One of our objects being to inquire into the bacteriological condition of the peritoneum at a distance from the primary lesion the first culture tube was inoculated with the platinum loop which was introduced into the abdominal cavity directly the peritoneum was opened. In the majority of cases there was at least sufficient fluid, whatever the nature of the disease, to furnish a loopful easily. When possible a cover-slip preparation was made of this fluid also. The second culture tube was inoculated either from the perito[illegible] the loop over the surface of the g[illegible] bourhood of the lesion. The fil[illegible] same region either with the exuda[illegible] of exudate, by drawing a sterile [illegible] surface of the intestine.

We may here point out that we believe the uniformity of our results to have been assisted largely by the operative methods employed by the surgeons of St. Thomas's Hospital. No chemicals are used for the instruments or any other part of the operation and consequently we avoided the errors which might have arisen had minute amounts of antiseptic solutions been introduced along with the exudates into our culture tubes. Our attention was drawn to this point in connexion with some cultures taken in the gynæcological theatre where such solutions are employed to some extent and where the growth of the organisms was undoubtedly retarded in that manner. When Dr. W. W. H. Tate, at our suggestion, very kindly discarded the chemical solutions until our cultures had been taken our results at once fell into harmony with those obtained in the other operating theatres. As a control experiment we took cultures in precisely the same manner from 12 consecutive cases of abdominal operations undertaken for exploratory purposes, in which neither obstruction nor inflammatory disease was suspected. The culture media invariably remained sterile. In the majority of the cases rubber gloves were used by both operators and assistants. Even then every precaution was taken in making the cultures to avoid any region which had been touched with the fingers.

Intraperitoneal Hæmorrhage.

There are at the present time those who, whilst admitting the bacterial origin of most diseases, are yet willing to accept the theory that peritonitis may, in certain conditions, be due to causes other than, and independent of, microbic infection. It is held that sterile fluids are capable, when introduced in sufficient quantities into the peritoneal cavity, of setting up a non-bacterial form of peritonitis and to this variety the term "chemical peritonitis" is applied. One result of our investigations upon the peritoneal exudate in cases of hæmorrhage has been not only to cast very considerable doubt upon the existence of chemical peritonitis but to guide us in the interpretation of other forms of peritonitis also.

So far as we are aware the bacteriology of intraperitoneal hæmorrhage has not hitherto been seriously investigated. The only mention of such a case which we have been able to find is by Malvoz, who, in 1891, in a case of ruptured tubal pregnancy, withdrew some fluid with a sterile aspirator before the abdomen was opened. The blood yielded a pure culture of the colon bacillus, but as there is nothing to show that the bowel was not traversed we cannot attach much importance to this observation.

We have investigated 20 cases of intraperitoneal hæmorrhage, 17 being due to extra-uterine pregnancy, two to rupture of the spleen, and one to rupture of the liver. In the cases of ruptured tubal pregnancy culture tubes were inoculated with the fluid which appeared directly the peritoneum was opened and others from the blood clot, whether old or recent, in the pelvis. Cover-slip preparations were made from the darker blood in the pelvis and these were stained by Gram's method. In three cases Gram-positive cocci were found in the films taken in this manner. By cultures the staphylococcus albus was isolated three times and the micrococcus albus once from the peritoneal cavity. *From the blood clot, however, a white staphylococcus was obtained from every case without exception.* In all the traumatic cases cultures from the blood were sterile and in two the staphylococcus albus was obtained in pure culture from the blood clot. Only one case of the whole 20 instances of intraperitoneal hæmorrhage was completely sterile and that was operated upon within two hours of the accident.

It is well known to gynæcologists of experience, and it is owing to the kindness of Dr. C. J. Cullingworth that we have become acquainted with the fact, that a pelvic hæmatocele, if left alone, may after a time become infected so as to give off, when opened, a musty or other unpleasant smell. Moreover, in days gone by pelvic hæmatocele was not an infrequent cause of pelvic abscess. This liability to infection, Dr. Cullingworth points out, is a strong argument in favour of operating upon all cases of pelvic hæmatocele. That a long-standing case is liable to infection, then, is well known, but that every case, even a few hours after the extravasation, becomes infected with micro-organisms has not hitherto, so far as we are aware, been ascertained. Again, cases of traumatic hæmorrhage which do not prove immediately fatal may, if the blood is in large amount, give rise to diffuse peritonitis and the following three cases reported by Mr. Herbert W. Page are good examples of such a sequel. He, however, did not attribute the peritonitis in his cases to bacterial infection. The first was a case of rupture of the spleen in a boy, aged 14 years. The abdomen was opened 24 hours after the accident when a large quantity of dark blood was found in the peritoneal cavity but there was no evidence of peritonitis. The intestines were distended and roughened. Death took place four days later and at the necropsy recent lymph was present in the abdomen. The second was a case of ruptured liver in a boy, ten years of age. 12 hours after the accident there were signs of peritonitis present and 12 hours later again, as the peritonitis was more marked, the abdomen was opened. The liver was found to be ruptured and there was a quantity of dark blood in the peritoneal cavity. The intestines were reddened and distended. At the necropsy the intestines were found to be inflamed and adherent. The third case was one of ruptured liver in a man, aged 22 years. The abdomen was opened 24 hours after the accident when a large quantity of dark blood was found in the peritoneal cavity. Death took place shortly after the operation. At the necropsy there was found diffuse peritonitis, the intestinal coils being glued together. Although no bacteriological examination was made, Mr. Page considered that the peritonitis which was present in all these cases was due to the fibrin ferment absorbed from the large hæmorrhages and quoted the opinion of Professor Orth that a considerable quantity of pure blood was sufficient to set up general peritonitis without any micro-organisms being present owing to the action of the fibrin ferment.

Tavel and Lanz, in their well-known work published in 1893, stated that in their opinion those cases of peritonitis which are found to be sterile are really examples of chemical peritonitis and are due to the products of bacteria rather than to the bacteria themselves. Harvey Cushing in his masterly monograph on acute diffuse gonorrhœal peritonitis has reached much nearer the truth than any other observer. He writes as follows: "Whether chemical peritonitis, so called, has any actual existence remains a question of doubt," and later, "it is possible that some forms of the chemical cases described by the surgeons may be, after all, of bacterial origin." Tavel and Lanz related several cases which they considered to be examples of chemical peritonitis, which are of such interest in view of our results that we briefly refer to them here.

One was a case of intestinal obstruction due to a band of four days' duration. The intestines were reddish brown and fibrin was present on the surface. There was blood-stained serum in the peritoneal cavity. A pure culture of a *white staphylococcus* was obtained both from the fibrin and the serous exudate. Another was a case of acute intestinal obstruction due to a volvulus in a man, aged 60 years. The intestines were enormously distended and there was a fibrinous peritoneal exudation from which a pure culture of a *white staphylococcus* was obtained. The third case was an example of suppurative cholecystitis with partial gangrene of the wall of the gall-bladder. A *white staphylococcus* was obtained from the interior of the gall-bladder in pure culture, although bacilli and chains of cocci were seen in film preparations of the pus. *A pure culture of a similar coccus was obtained from the inflamed peritoneum.* Two other cases are also reported in their paper but in both instances cultures from the inflamed peritoneum remained sterile. Although Tavel and Lanz found a coccus in three of their five cases they preferred to consider that the organism was present as a contamination and that these were really instances of chemical peritonitis. Gruber and Durham have pointed out that the failure to find microbes in peritoneal fluid is not sufficient evidence to stamp a case as chemical peritonitis, inasmuch as they may be present upon the peritoneal surface and not in the exudate. This we have found to be true in a large number of cases and attention will be directed to it again when we deal with the peritonitis associated with intestinal obstruction. As we shall show presently, we have found the white staphylococcus not only in intraperitoneal hæmorrhage and intestinal obstruction but also in many other varieties of peritonitis. We, therefore, consider that we have sufficient evidence to justify the opinion that chemical peritonitis does not exist but that the cases to which the name has been given are really instances of an infection of the peritoneum with the staphylococcus albus. We intend to discuss every important fact in connexion with this coccus after we have considered other varieties of peritonitis. We shall be able to show that this organism is important not only in intraperitoneal hæmorrhage but is the most important organism in the bacteriology of peritonitis.

The changes which ensue as the result of blood extravasation into the peritoneal cavity appear to be similar whatever the source of the hæmorrhage, provided that there is no communication either with the exterior or with the bowel. In the traumatic cases the time interval between the onset and the operation was from two to five hours; in the cases of extra-uterine pregnancy it varied from 24 hours to three months. As we have seen, the only example in which we failed to find a white staphylococcus was a case of ruptured spleen operated upon only two hours after the accident.

We have examples of every variety of blood extravasation, from the recent widespread hæmorrhage down to the old completely encysted hæmatocele. The appearances on opening the peritoneum vary in degree but not in kind. When the intestines are bathed in blood even after a very short time the peritoneum appears reddened and in the most infected portions the intestines are more or less distended. In the cases where the hæmorrhage has been arrested or is only proceeding slowly these changes are limited to the intestines immediately in contact with the extravasated blood. That peritonitis is present here is evidenced by the very fact of the walling off of the hæmatocele by intestinal agglutination. In every case of hæmatocele, even the oldest, there was an appreciable quantity of clear or slightly blood-stained exudate in the peritoneal cavity immediately overlying the hæmatocele, and this fluid in two instances, one of one month's duration and one of three months, was found to contain the staphylococcus albus, the same organism being also present in the hæmatocele itself. Of the 20 cases four proved fatal, two being examples of ruptured tubal pregnancy, and two of hæmorrhage from ruptured solid viscera. The fatal cases were all very collapsed when operated upon and died in a few hours. One traumatic case recovered after splenectomy and peritoneal lavage, and 15 of the rest after removal of the Fallopian tube and lavage. The abdomen was closed in every case but one, and that was drained per vaginam. 13 healed by first intention, but one of these became the seat of a late suppuration. In three instances suppuration of the abdominal wound occurred, and from the pus of one of these a pure culture of the staphylococcus albus was obtained.

In cases of ruptured tubal pregnancy a febrile condition is usually present both before and after operation, which is quite independent of local suppuration or of pulmonary or other complications. The fever lasts for a varying period after operation and in most cases its range is not excessive, but in nearly every instance it is remarkably higher and more constant than after any other operation which runs an aseptic course. Slight as are the pathogenic properties of the staphylococcus albus we are of opinion that the febrile disturbances so frequently found after effusion of blood into the peritoneal cavity are due to the presence of this organism and not to any hypothetical toxic substance produced by the coagulation of the blood.

INFLAMMATION AND PERFORATION OF THE HOLLOW VISCERA.

Under this heading we include the gall-bladder, the stomach, the duodenum, and the intestines with the exception of the appendix vermiformis, which will be considered separately.

Cholecystitis and perforation of the gall-bladder.—With regard to the gall-bladder, it is difficult to form an opinion as to the bacteriology of peritonitis arising from this cause owing to the scantiness of the material at our disposal. Recently J. T. Hewitson has published his results of the examination of bile taken from cases of cholelithiasis at the time of operation. He investigated 19 such cases, of which only three proved to be sterile. In the remaining instances the colon bacillus was found eight times, the streptococcus pyogenes four times, other cocci nine times, and other bacilli four times. He also tested the action of sterile bile upon a variety of pathogenic organisms and concluded that it possesses no antiseptic property whatever. Naunyn, Gilbert, Girode, Dupré, and others have found normal bile to be sterile. One of us recently found ten cubic centimetres of bile taken from the gall-bladder at an operation to be sterile under both aerobic and anaerobic conditions. Fraënkel reported a case of perforation of a diseased gall-bladder where the staphylococcus albus and the streptococcus pyogenes were found in the peritoneal exudate.

Only two instances of cholecystitis are included in our series. The first case occurred in a man, aged 68 years. This patient had had a history of gall-stones for many years. He had been very ill for 17 days before admission, with abdominal pain and fever. When admitted the temperature was 101° F. A small localised collection of necrotic material was found outside the gall-bladder, communicating with the interior by a perforation over a stone. There was a quantity of sticky, purulent, bile-stained fluid around the stones in the gall-bladder. The peritoneal cavity at a distance was found to be sterile. A pure culture of a streptococcus was obtained from the necrotic material around the gall-bladder and also from the interior of the viscus. The organism resembled the streptococcus pyogenes in most of its cultural characters, but although several tubes of litmus milk were used it failed in every instance either to acidify the litmus or to thicken the milk. When

the coccus was injected into the vein of a rabbit's ear no local erysipelas resulted and although the animal was ill for several days it finally recovered. The same organism was non-pathogenic to guinea-pigs. This coccus may have been
an attenuated pyogen
We are not justified, I
coccus of Rosenbach.

The second case concerned a woman, aged 35 years, suffering from empyema of the gall-bladder. The peritoneal cavity was sterile. The thick, white, odourless pus in

recovered.

Perforated gastric ulcer.—A well-known physician once said that "where facts are barren theories are numerous." It would be difficult to find a more suitable illustration of this truth than that afforded by perforating ulcer of the stomach. It is, however, only with reference to the peritonitis produced by this accident that we are at present concerned. Very little work has been done upon the bacteriology of gastric perforations. Hewitson, from experiments made with gastric contents taken during operations, concluded that in half the cases the contents of healthy stomachs are sterile and that in the other half either the

was present in every one of our cases.

Lately, owing to the work of A. Ghon, the pneumococcus has been credited with an important share in the causation of gastric perforation. This observer reports four cases which, however, are not as fully described as one would wish when we consider the important bearing which this communication must have on future work. It is significant that only one of these cases of perforation of the stomach was due to a simple ulcer. Jensen is stated to have isolated the pneumococcus from the peritoneal exudate in three cases of perforated gastric ulcer. Brünner collected 22 cases of perforated gastric ulcer which had been examined bacteriologically and found that four were due to the pneumococcus. Other observers have claimed, but with insufficient evidence, that streptococci and staphylococci are the cause of the active changes which take place in the stomach wall.

It will thus be readily seen that the bacteriological investigations of this very important disease and of its most important complication have been found to be of little value. It is therefore with a feeling of some reserve that we bring forward our results. This investigation has led, however, to most constant results. We have isolated a strepto-diplococcus from the edge of the ulcer in every case; from the peritoneal exudate in four instances out of a total of seven. We have also obtaine
the pleural sac and from the
following on perforated gastric
diplococcus has been isolated and also from a perigastric abscess. A full account of this research will now be given and although it is not our wish to suggest that this organism which has been found in every case, without exception, is the cause of the disease, yet we do claim that these results are of considerable importance and will serve as a basis for future work.

was much more frequently found
than as single coccus. We did
not observe a capsule on any occasion. The organism was non-motile.

Staining reactions.—This coccus in the large majority of cases, whether direct from the patient's tissues or from artificial culture media, failed to retain Gram's stain. In one or two instances it was found to stain slightly by Gram's method but a true positive reaction was not seen. The coccus stained well with the aniline dyes.

Cultural characters.—These were as follows:—

Agar.—In every case the organism grew well on the surface of agar. The colonies were always small, of about the size of an active streptococcus colony. They appeared to be of about the size of a pin's head, even after several days' growth, and opaque, delicate, quite isolated, with no tendency to form a continuous streak, faintly granular, and with a regular margin.

Broth.—The growth in this medium was of the same character in every case—viz., sandy deposit—but quite clear above. When the broth-tube was shaken a distinct but finely granular deposit was visible.

Litmus milk.—This medium was acidified in either 48 or 72 hours. No thickening or clotting occurred in most cases even at the end of a month's incubation. In two instances, however, the milk thickened at the end of 48 hours and a distinct clot formed in eight days in the former example.

Jelly.—In three instances the surface of growth was noticed on the jelly media. In each case there was a very fine pin-head growth forming isolated points with no tendency to coalesce. The medium was not liquefied even at the end of one month's incubation at 22° C. The colonies were almost transparent.

Neutral red jelly.—The colour of this medium was unaffected.

Potato.—No growth was obtained.

Glucose broth (anaerobic).—In those cases in which anaerobic methods were used the growth appeared to be similar to the aerobic growth.

Pathogenicity.—A 24-hours' broth culture was used for inoculating guinea-pigs and mice, either or even both subcutaneously and intraperitoneally. We failed to kill any of these animals with this organism. In many cases the animals were extremely ill but death never occurred, and we did not observe any pathological lesion at the necropsies on animals inoculated with the culture of this coccus.

Agglutination tests.—In no instance was the agglutination test found to be of any value.

We have given the chief points which have been investigated so far as regards this organism. Has it any relation to the streptococcus pyogenes, pneumococcus, or other pathogenic organism? It is quite evident that this coccus has very low pathogenic properties in the human being, in the large majority of cases. It is found, as we have shown, in the peritoneal cavity in cases of perforated gastric ulcer and yet the patients do not die from peritonitis. It is true that it was found in the pus from a case of subphrenic abscess in conjunction with the staphylococcus albus but the peritoneum seems to be able to deal with the organism better than the tissues—by no means a new idea as regards micro-organisms and the peritoneum. One would imagine that this coccus is sufficiently pathogenic in the human tissues to produce the well-known ulcer of the stomach, as we have found it in every case at the edge of the ulcer. There is not sufficient evidence from our investigation to warrant this view, although one would not expect a streptococcus or any other organism to be present in every case if it had nothing to do with the disease. In sections of the stomach wall around the site of perforation of an ulcer large masses of cocci can be seen and also diplococci, but no true streptococci. Several observers have drawn attention to the presence of cocci in the gastric wall in cases of ulceration, but it by no means follows that these organisms are therefore the cause of the condition.

The nature of this strepto-diplococcus.—It will be evident from these points to which we have drawn attention in the life-history of this coccus that its cultural properties are not constant in every case. This, however, is common to most micro-organisms, but on the whole the morphology, the cultural characters, the staining properties, and the pathogenicity are fairly regular. It is now generally recognised that various cocci which have been described by different authors as the streptococcus pyogenes are really nothing more than streptococci and not the true coccus of Rosenbach. The same may be said of the pneumococcus and also of many other micro-organisms. The streptococcus which we have described, however, differs in so many respects from the streptococcus pyogenes that it would be impossible for anyone to consider the two micro-organisms as one. In the first place, it was Gram-negative. The constant tendency to form a diplococcus arrangement is quite unlike the streptococcus pyogenes. The organism resembled the streptococcus pyogenes in the fact that it did not alter the colour of neutral red jelly. The individual colonies on agar are perhaps larger than in the case of Rosenbach's coccus. The pathogenic properties of streptococci certainly vary considerably. A streptococcus which has produced severe changes in the tissues of men may be found to have very little effect when inoculated into a susceptible animal. We failed to find any evidence of erysipelas at the site of inoculation in our animals. As already stated, this strepto-diplococcus failed to kill, although in almost every case the inoculated animal was ill for some hours after the inoculation. There is one point which is quite certain, that if this coccus were the streptococcus pyogenes the perforation of gastric ulcer would be followed by almost certain death. There is not the slightest reason to discuss the relationship of this organism to the pneumococcus as they differ perhaps even more than in the case of the streptococcus. We are, therefore, inclined to allow this strepto-diplococcus to remain unclassified.

In six cases the peritoneal cavity was flushed out after suture of the ulcer and in one practically no washing was done. This last case had been perforated 24 hours, the small aperture was closed with lymph at the time of operation, and the signs of peritonitis were slight. No drainage was employed and the wound healed by primary union. Recovery took place in five instances (though one patient died a month later from portal pyæmia), the wound in the two cases where drainage was not employed having healed without suppuration. Two patients died, one on the tenth day from pneumonia but without any peritoneal symptoms and the other from diffuse peritonitis soon after the operation. This last was the only case in which the colon bacillus was found and at the necropsy there was present a condition of universal peritonitis which exhibited the peculiar sticky exudation seen in the peritoneal cavity of guinea-pigs killed with this organism.

As in the case of acute perforations, so it is with localised abscesses dependent upon gastric ulcer. In one instance there was a local perigastric abscess adherent to the anterior abdominal wall in a man, aged 32 years, who, after a long history of gastric symptoms, had been rather acutely ill for a fortnight before operation. The thick odourless pus showed the same strepto-diplococcus to be present. In another example a left-sided subphrenic abscess was opened 25 days after operation for an acute perforation. The pus was odourless, thick, and cream coloured, and had to be reached through the diaphragm. Both the pleural sac, which was inflamed and moist, and the abscess gave a pure culture of the strepto-diplococcus, which both in the peritoneal exudate and in the edge of the ulcer had been found at the first operation.

In the cases of gastric ulcer the operation was undertaken at times varying from six to 32 hours after perforation. In all there was a large amount of fluid in the peritoneal cavity, which was thin, turbid, and sour-smelling. In two examples it was distinctly greenish; in one, where the perforation was minute and closed by lymph, the fluid was quite clear and sticky. The intestines were, as a rule, reddened but very little distended; what signs of peritonitis were present were usually only at all obvious in the immediate neighbourhood of the perforation, where flakes of lymph were commonly seen. The only instance in which the peritonitis was observed to be at all extensive and in which intestinal distension was marked was the instance in which the colon bacillus was found and which succumbed to peritonitis. This is further proof of the great importance of the colon bacillus in peritonitis. It is also of interest that although this bacillus was isolated in this instance the strepto-diplococcus also was present. We should expect, if certain popular theories were correct, that the bacillus would have outgrown the coccus.

Perforated duodenal ulcer.—In these cases we find a bacterial condition rather different from that obtaining in the gastric cases. In the four examples in our series the perforation was situated in the first part of the duodenum and the appearances afforded by the peritoneum and the exudate were similar to those seen in the gastric cases. In no instance, however, was the strepto-diplococcus isolated from the exudate, which was sterile in three cases and contained the colon bacillus in the remaining one. The gut surface once showed the staphylococcus albus; on two occasions the staphylococcus albus was isolated from the edge of the ulcer, and once the colon bacillus together with the strepto-diplococcus. The time that had elapsed between onset and operation was in two instances four hours; in one, nine hours, and in the fourth, 19 hours. In every case the ulcer was sutured and the abdomen was washed out. Two recovered, one with and one without drainage, and in both instances the wounds healed kindly. Of the two fatal cases one succumbed to pneumonia on the third day but with a healthy peritoneum; the other died from diffuse peritonitis and this was the one example in which the colon bacillus was present in the peritoneal exudate; the perforation had occurred 19 hours before operation. In this instance a large quantity of turbid, sour-smelling fluid and some gas were present in the peritoneal cavity. Large numbers of polynuclear cells and Gram-negative bacilli were present in the exudate. The colon bacillus was found in pure culture in the exudate and the same organism together with the strepto-diplococcus in the edge of the ulcer. The coccus was not fully worked out in this case.

Perforation of the jejunum.—We mention separately one remarkable instance of perforation of a peptic ulcer of the jejunum which occurred 22 months after gastro-enterostomy for simple gastric ulcer. The patient was a male, 30 years of age, and the acute symptoms had been present for four hours before the operation. A large quantity of clear, odourless fluid was free in the peritoneal cavity and there was a small perforation in the jejunum close to the anastomotic opening, around which the peritoneum was reddened and covered with flakes of fibrin. Elsewhere there was scarcely any sign of peritonitis. The exudate showed large numbers of degenerated cells and a few polynuclear cells but no organisms. From three situations—namely, the exudate, the edge of the ulcer, and the surface of the jejunum—the staphylococcus albus was obtained in pure culture. The ulcer was invaginated, the abdomen was flushed out, and the pelvis was drained. The patient recovered, the wounds having healed well.

Perforation of the ileum.—In this class there are four examples, one being due to a bullet wound, one to a chronic ulcer of undetermined nature, and two to typhoid ulcers. The gunshot wound of the ileum occurred in a healthy boy, aged 18 years, who was operated upon 20 hours after the accident. There was a little bloody exudate amongst the slightly reddened but not distended coils of small intestine. Two minute perforations and three bruises were found in the [illegible] ileo-cæcal valve, the wound [illegible] through the right rectus at [illegible] ore operation the only signs [illegible] slight tenderness round the [illegible] pulse-rate, which reached [illegible] face of the intestine at a distance was found to be sterile; the blood-stained fluid around the perforations showed only blood in films and gave a pure growth of the staphylococcus albus. The perforations were closed, the intestines in the neighbourhood were washed over with sterile saline solution, and the abdomen was closed without drainage. The wound healed by primary union. We regard this case as forming a link between those of intraperitoneal hæmorrhage without intestinal lesion on the one hand, and perforations due to disease, on the other. In the former there is no intestinal perforation, in the latter the contents of the perforated intestine are in a state of exalted virulence, whilst in this instance the intestine was in an absolutely healthy condition when the perforation took place.

The difference in prognosis in perforation of the intestine according to whether the bowel is or is not diseased at the time of perforation is obvious when we look at the mortality of the two conditions. In diseased conditions, perforated appendix or typhoid ulcer for instance, the mortality is not less than 70 per cent., but in gunshot wounds in civil practice, of which we have collected 15 cases from various sources, the mortality was only 20 per cent. It is only fair to say, however, that these cases are usually operated upon earlier but this fact would scarcely make the difference between 20 and 70 per cent.

PERITONITIS IN TYPHOID FEVER.

The rôle of the bacillus typhosus in peritonitis is a very doubtful one. Curschmann believes that cases of peritonitis without perforation sometimes occur during attacks of enteric fever and are characterised by mild onset, irritative symptoms in the right iliac fossa, and perityphlitic exudation, and that the course of such cases is relatively favourable. He quotes a case recorded by Murphy in which there was peritonitis without perforation and five cases reported by Gardner in which a fatal peritonitis occurred without perforation. The Munich necropsies show that peritonitis without perforation occurs in 2·2 per cent. of the fatal cases. Cushing, also believing that a localised peritonitis may occur without perforation, considers such a condition to constitute a pre-perforative stage. But of the bacteriology of non-perforative peritonitis in typhoid fever we know nothing.

Much of our knowledge of typhoid fever at the present day is derived from the work which has been done at the school of Baltimore. Cushing published his excellent monograph on Intestinal Perforation in Typhoid Fever in the Johns Hopkins Reports in 1898. We wish to refer to the chief points in this paper before giving the details of our own work. His cases are as follows:—

CASE 1.—The peritoneal [illegible]
symptoms of perforation [illegible]

preparations of the fluid [illegible]
but no organism [illegible]
was sutured. [illegible]
Cultures taken [illegible]

CASE 2.—Intestinal perforation occurred in the fifth week of [illegible]

We shall have to refer more fully to these valuable observations of Cushing when we come to discuss the peritonitis of streptococcic origin. The typhoid bacillus has been obtained from the peritoneal exudate in perforative typhoid fever both by Flexner and Hays; from an example of diffuse peritonitis due [illegible] by Körte; and Klein is [illegible] bacillus from the periton[illegible] peritonitis. These cases appear to be the few recorded, if not the only, examples of peritonitis from which the typhoid bacillus has been isolated. We must remember that a bacteriological examination of the peritoneal cavity in perforative typhoid fever has only been made in a few of the great scientific medical schools in America and on the continent, if we can judge by the literature. So much Keen states in his book on "The Surgery of Typhoid Fever" that he only knew of a single instance in which a bacteriological examination was made of the contents of the peritoneum in typhoid perforation. I[illegible] cases of typhoid perforation were recorded at [illegible] of London but a bacteriolog[illegible] [illegible]neal exudate was omitted in every case.

Hays reported two such cases, finding the bacillus typhosus in one and the streptococcus pyogenes in the other. Both patients died. Manahan investigated two cases at the time of operation. In one, ten hours after perforation, the films were sterile and the cultures showed only the colon bacillus. The serum reaction was positive and the patient recovered. In the second case the staphylococcus albus and the colon bacillus [illegible] The patient died. Varvach [illegible] showed [illegible]

We are able to [illegible] which we have made a complet[illegible] of the peritoneal exudate, as [illegible] We have included the clause "[illegible] so" because surgeons usually perform a comparatively limited operation for this complication of typhoid fever and therefore it is generally impossible to make cultures of the peritoneal exudate at a distance.

[illegible] eight years. About two ounces [illegible] ritoneum and also a [illegible] was found about four [illegible] The intestines were [illegible] numbers of poly- [illegible] uniformly [illegible] nuclear and mononuclear cells we[illegible] tions of the peritoneal exudate [illegible] negative bacilli. The turbid fluid [illegible] cavity at the time of operation [illegible] sent immediate[illegible] inoculated w[illegible]

[illegible] ination reaction. This bacillus [illegible]

[illegible] of 30 years. There were about [illegible] portion of the abdomen and also much free gas. Two minute perforations were found close to the ileocæcal valve. Both perforations were invaginated by sutures and the lower half of the peritoneal cavity was washed out with normal saline solution. The patient died 48 hours later. Cover-slip preparations were made of the peritoneal exudate at the time of the operation. Large masses of polynuclear neutrophiles were seen in the films, many of which were phagocytic. Gram-positive cocci and Gram-negative bacilli were also seen. Aerobic and anaerobic cultures were made from the fluid in the peritoneal cavity. *Three strains* of the bacillus coli were isolated from this exudate but two of these strains which were fully examined were found to differ not only in their cultural characteristics but als [illegible] The importance of these [illegible] not be overestimated and [illegible] subject in a subsequent lect [illegible] which grew on the agar plates [illegible] but failed to give any reaction. A staphylococcus which stained by Gram's method was present in the film preparations of the peritoneal exudate and in the original cultures both aerobic and anaerobic but we did not obtain any colonies of the coccus on any of the plates.

Lastly, although Flexner and Vincent have found streptococci frequently in the peritoneal cavity of cases dead from perforation of the intestine in typhoid fever we have not observed this coccus in either of our cases examined at the time of operation.

Turning now to the clinical aspect of these two cases we find that perforation occurred in the third and sixth week of illness and that the operation was undertaken respectively 48 and ten hours after perforation. Both were treated by suture, limited lavage, and drainage, and both patients died. The bacillus typhosus was found in neither case; in one the colon bacillus only was found and in the other the colon bacillus and the staphylococcus aureus. In both the post-mortem examination showed intense universal peritonitis to be present. In these cases, owing to the limited exposure at the operation, we were unable to ascertain the bacteriological condition of the peritoneum in a remote region. Ashurst collected from the literature records of 326 cases of intestinal perforation during enteric fever which were submitted to operation. The mortality was 74 per cent. Now, this death-rate is lower by about 6 per cent. than that of perforative appendicitis, which when we consider that in the one case the patient is debilitated by two or more weeks of an exhausting illness, whilst in the other he is usually attacked when in perfect health, is sufficient to excite our curiosity. It is even most striking when we consider that operations undertaken for perforation occurring during a relapse show a lower rate of mortality than those which occur in an initial attack. It may be that one contributing factor is that the patient is already under skilled observation, so that a diagnosis can be made and operation proceeded with earlier. We venture to think that there are other explanations also. In the first place the gradual thinning and distension of the intestine will have allowed time, in the cases of typhoid fever, for the natural protective mechanism of the peritoneum to have been called into play; in the cases of perforated appendix, on the other hand, the lethal organisms are suddenly, as it were, launched upon an unprepared peritoneum. Again, the patient is usually so ill, in the cases of typhoid fever, when operated upon that the surgeon not only operates with the utmost rapidity, a factor of no little importance in all acute abdominal operations, but dares not douche and scour the peritoneum with the same heroism as he sometimes applies to the appendix cases.

Perforation of a malignant growth of the colon.—The following instance of perforation of a carcinoma of the colon illustrates well the rôle played by the staphylococcus albus in peritonitis and is in complete harmony with the appendicitis cases. A woman, aged 60 years, had had an abdominal tumour accompanied by chronic constipation for nine months. For five days the tumour had been more painful. When admitted the temperature was 102° F. and on the previous day she had had a rigor. The abdomen was rather distended but obstruction was not absolute. The abdomen was opened in the mid-line, when omentum of normal appearance presented. This proved to be sterile. Proceeding towards the tumour the intestines in its neighbourhood were found to be reddened but not distended; cultures from the gut surface gave a pure growth of the staphylococcus albus. Close to the tumour there was some clear fluid which also gave a pure culture of the staphylococcus albus. Film preparations of this fluid contained large numbers of healthy polynuclear cells but no micro-organisms. The peritoneal cavity was then packed off with strips of gauze and a foul abscess was opened. Film preparations of the pus showed numerous degenerated cells as well as Gram-positive cocci and Gram-negative bacilli. From the cultures were isolated the colon bacillus and the staphylococcus albus. We did not obtain a growth of anaerobic organisms although every precaution was used. The patient died on the fourth day and at the necropsy a condition of intense diffuse peritonitis was found. There is little doubt that the colon bacillus had invaded the general peritoneal cavity owing to the opening of the abscess and given rise to the fatal peritonitis. We have here, however, a clear example of the protective influence afforded by the staphylococcus albus and its attendant phagocytic cells, which, owing to the slow progress of the disease, had been able to exert a restraining power on the colon bacillus and prevented this organism from terminating the patient's life earlier.

THE STAPHYLOCOCCUS ALBUS IN PERITONITIS.

We have considered it advisable to refer to the coccus which we have isolated from the peritoneal cavity in ruptured tubal gestation, appendicitis, and in all other varieties of peritonitis, as the white coccus or the staphylococcus albus. The organism which was described by Rosenbach as the staphylococcus pyogenes albus sometimes produces abscesses when injected subcutaneously into guinea-pigs and rabbits and may produce septicæmia and pyæmia when inoculated intravenously into these animals. The white coccus which we isolated from our cases of peritonitis differed from Rosenbach's coccus as regards its pathogenicity and therefore it is perhaps advisable to omit the term pyogenic when referring to the coccus present in our cases. Professor W. Welch preferred to name the organism which he isolated from aseptic wounds, stitch abscesses, and also from the peritoneal cavity in a case of peritonitis, the staphylococcus epidermidis albus. He considered that it was probably an attenuated variety of the staphylococcus pyogenes albus. We can do no better than follow in the footsteps of so eminent an authority as Professor Welch and omit the term pyogenes.

TABLE I.—*Showing the Number and Variety of Cases from which the White Coccus was recovered from the Peritoneal Cavity in Peritonitis.*

Table.	Nature of case.	Number of cases in which the white staphylococcus was isolated.	Number of cases in each table.	Number of cases in which a staphylococcus was present but not identified.
1	Ruptured tubal gestation.	17	17	0
2	Intraperitoneal hæmorrhage from other causes.	2	3	0
3	Salpingitis.	1	8	1
4	Ovarian cystitis.	2	3	0
5	Strangulated hernia.	12	47	1
6	Intestinal obstruction.	24	53	
7	Inflammation and perforation of the hollow viscera.	10	21	1
8*a*	Acute appendicitis with diffuse non-perforative peritonitis.	4	11	0
8*b*	Acute appendicitis with diffuse perforative peritonitis.	3	17	1
8*c*	Appendicitis with local abscess formation.	15	40	10
8*d*	Appendicitis complications.	5	9	0
8*e*	Interval cases of appendicitis.	10	16	1
9	Post-operative peritonitis.	2	7	0
10	Septicæmic peritonitis.	1	6	0
11	Exploratory cœliotomy.	0	12	0
	Total	108	270	17

Morphology.—This organism was found to be identical morphologically with the various types of staphylococci. It stained well by Gram's method and with the various aniline dyes. The individual cocci were smaller when the organism was grown anaerobically and in these instances the cocci showed less tendency to retain Gram's stain.

Cultural characters.—The organism was found to be a facultative anaerobic. It did not decolourise Weil's medium and failed to produce gas in any medium containing glucose.

Broth.—Marked turbidity of the medium occurred and a corkscrew-like deposit on shaking the culture-tube was obtained in every case within a period of 24 hours.

Agar.—A pure white streak along the line of the needle with irregular margins due to isolated colonies was obtained on every occasion. In some instances the growth on agar was dry but in the large majority of cases it was moist.

Jelly.—A growth was seen in every instance within 24 hours which gradually increased. Liquefaction of the medium generally occurred about the second to the fifth day. In two examples we failed to obtain any liquefaction.

Neutral red jelly.—The cultural characters were similar to those which have been already mentioned in the case of ordinary jelly. The colour of the medium was changed to yellowish-brown in 13 examples, a change which usually took place within eight days, at 22° C. The colour remained unchanged in 11 instances.

Litmus milk.—This was acidified in every instance, usually within 46 hours. It was generally thickened within 48 hours and clotted in from three to four days. In three instances clotting did not take place until after the tenth day. In many instances, especially if the clotting was slight, the casein was gradually redigested.

Potato.—The growth on potato could seldom be described as luxuriant. Numerous white dots on the surface of the medium which after two or three days' growth gradually formed a continuous streak were of common occurrence. In a few instances only a very slight growth occurred.

Neutral red broth.—This medium was employed in but a few instances, so that it is impossible to form any definite opinion as to its value. In most instances in which it was employed we noticed that the neutral red colour was changed for a bright pink colouration.

Indol reaction.—This reaction was not present in those instances in which the test was employed. This, of course, refers to both young cultures in peptone water and also cultures of from six to ten days old.

Surface colonies on jelly plates.—Small but distinct ours' growth at 22° C. At colonies when examined small raised white points shown to have a distinct and regular margin, while each colony was definitely granular.

Pathogenicity.—Young broth cultures of the white coccus obtained from various cases of peritonitis were injected into the peritoneal cavity of animals. We usually noticed that the animals were ill for several hours but usually were perfectly well within 24 hours. In some instances inoculation of the coccus into the peritoneal cavity of guinea-pigs did not produce any obvious effect. We have shown, however, that the inoculation of this organism into the peritonial cavity of guinea-pigs produces a large quantity of clear effusion into the peritoneal sac within an hour of inoculation. Large numbers of phagocytes also take an active part in freeing the peritoneum from this coccus. These observations show that it is impossible to judge an inoculation experiment without a very exact necropsy. In some instances this organism was injected into the peritoneal cavity of guinea-pigs prior to an injection of the colon bacillus, with the most remarkable results which are fully dealt with elsewhere. Subcutaneous injection of the coccus into various animals seldom produced more than an inflammatory swelling of about 48 hours' duration. Occasionally the swelling subsided much more rapidly without any obvious ill effect. In no instance, however, did suppuration occur. An induration around the site of inoculation in those cases in which the white coccus had been injected subcutaneously was frequently noticed. We very much regret that we failed to inject the white staphylococcus into the blood stream of rabbits, as this is often found to be a ready means of forming an opinion of the pathogenic properties of this coccus.

Agglutination reactions: technique.—In every case a 24-hours' agar culture was employed. An emulsion was made with 0·85 per cent. normal saline solution; sometimes this emulsion but when ased to 0·1 per cent., as the case of the plague control experiment was, of course, carried on during the whole period of each observation.

It is usually considered at the present day that complete loss of motility and diffuse and "tight" agglutination within a period of 30 minutes with a dilution of 1 in 150 are diagnostic of typhoid fever. So far as we are aware the agglutination reactions of the staphylococcus albus are unknown, whilst only a small amount of work has been published regarding agglutination experiments with the staphylococcus aureus. Otto concludes that of the many varieties of staphylococci there is only one which is really pathogenic to man. This variety, he says, may easily be distinguished by its strictly specific agglutination reaction with the serum of an animal immunised against this pathogenic variety. It is, however, generally recognised that pathogenicity and agglutination bear no constant relation to one another and, therefore, for this, amongst other reasons, we cannot place any reliance upon these observations of Otto.

It is impossible at present to lay down any fixed rule as to what constitutes a positive or a negative staphylococcic reaction and we have, therefore, been obliged, for the purposes of this work, to fix an arbitrary standard. We have tested the agglutination reaction of the staphylococcus albus, isolated from various cases of peritonitis, with the patient's own serum and in certain instances with the serum of other patients, in 46 cases. In 26 instances there was no reaction with a dilution of 1 in 10. In seven instances well-marked clumping of the cocci occurred with dilutions of 1 in 10, 1 in 20, and 1 in 50 within a period of one hour, and in one instance with a di marked clumping a slight reaction w period of 60 minutes. In four cases good reactions occurred with dilutions of 1 in 10 and 1 in 20 within a period of one hour but no reaction was obtained with a dilution of 1 in 50. In two cases there was only a slight reaction with dilutions of 1 in 10 and 1 in 20 in 60 minutes. In two examples some reaction was obtained with a dilution of 1 in 10 but not with any further dilution. None of these cocci when tested with the serum of a normal person gave any reaction whatever. If we now turn to the length of time that the patients had been ill before the operation and divide it into periods a very striking result is obtained. In six cases the illness had lasted for less than six days and none of these gave any reaction. In the 12 cases which gave a reaction with a dilution of 1 in 50 the length of history lay between six days and 16 weeks. In the four which gave a good reaction with 1 in 20 but none with 1 in 50 dilution the illness had lasted for from one to three months.

It is scarcely fair to compare two organisms differing so widely in their degree of pathogenicity as the staphylococcus albus and the bacillus typhosus, but we may say that in one respect they resemble one another in the agglutination reactions A well-marked typhoid serum reaction rarely occurs before the tenth day of illness and we see very much the same to be the case with the staphylococcus albus; no reaction was obtained in a case of less than six days' history.

Browne and Crompton, working in the clinical laboratory of St Thomas's Hospital, have obtained the following interesting results as to the length of time in which the typhoid agglutination reaction persists after an attack of typhoid fever. With a dilution of 1 in 50 they found that there were only two instances in which the reaction was positive seven months or more after the attack of typhoid fever. In 50 per cent. the reaction was positive from one to six months after the attack, while a large number of the negative cases reacted to dilutions of 1 in 10 and 1 in 20. They considered a reaction to be positive when complete loss of motility and diffuse "tight" agglutination occurred within a period of 30 minutes. We do not know how long it may persist in the case of the staphylococcus albus, but the evidence which we have leads us to the conclusion that the agglutinative properties may last some months, as in the case of patients who returned for appendicectomy several weeks after the healing of an abscess, and in whom the staphylococcus was still found to be present in the peritoneal cavity. The case in which the best reaction was obtained was one of great interest. An appendix abscess had been opened 11 weeks previously and had healed. The patient had been taken ill again three days before admission and was found to be suffering from diffuse peritonitis. The staphylococcus albus, which was isolated from beyond the region which contained the colon bacillus, was rapidly and "tightly" agglutinated by the patient's serum. Recovery took place.

chest or abdomen, was diminished on anæsthetising a patient. I have often verified this and have been disappointed at the partial or complete disappearance of superficial dulness in cases of appendicitis and empyema when the patient has been anæsthetised for operation. It is easy to understand how this may be caused in such a condition as an abscess or mass of lymph around an inflamed appendix. The tightly contracted muscles, nature's involuntary protection against external injury, even such slight injury as percussion, squeeze the unaffected coils of intestine away from the space between the abdominal walls and the painful lump, but when they are relaxed the intestines slip in again and the previously dull area becomes resonant. Consequently upon this the outline of the lump becomes much more easily determinable, but as was pointed out by Dr. W. Moxon the risks of manipulation are increased. He told of a case of appendicular abscess which came unscathed through the ordinary investigations of a hospital ward but was ruptured by manipulation with what was considered to be due care when the patient was under the influence of an anæsthetic. It is not so easy to explain the mechanics of this phenomenon in the chest, and, indeed, it is by no means so frequently observed. It must depend upon a more free movement of the chest wall when the act of breathing becomes less painful or less suggestive of the possibility of pain, a movement which causes greater expansion of the lung. This will increase the resonance of the already resonant part and may, as in the case of the appendix abscess, drive the lung between the dull mass (say the liver or spleen covered by the diaphragm) and the chest wall which were previously in contact.

The practical importance of these facts is great. They show that a dulness which disappears under an anæsthetic must not be neglected, but it must be suspected that adhesions do not extend so far as they might before the administration of the anæsthetic be supposed to do. Thus, if the case be one of appendicitis the cautious surgeon will not open the abdomen immediately over the swelling but will separate the peritoneum from the fascia transversalis for some distance backward and thus hope to open the abscess without interfering with the part of the peritoneum where there are no adhesions. In the case of a suspected empyema in which the dulness disappears under the anæsthetic he will probably find that it is one of pyopneumothorax and that it is the change of position of the patient which has brought the gas which previously occupied the upper part of the cavity into the field of operation and he must not forget that a small amount of gas may be responsible for an extensive area of resonance.

I will now make another digression. In some cases of ascites percussion gives a more extensive area of dulness when the finger is pressed lightly on the abdomen than when it is pressed more firmly. This means that a thin layer of fluid intervenes between the hollow viscera and the abdominal wall. Firm pressure with the finger forces the fluid away and the percussion is then made upon the subjacent coils of intestine. No one who has ever tapped an ascitic abdomen doubts that this is generally the case, although in a general way it may be stated that the intestines are floated up by the fluid. If the amount of fluid is large there comes a time when this floating process is no longer possible because the intestines are anchored to the spine by the mesentery. A somewhat similar phenomenon may occasionally be noticed where the liver is large and some coils of intestine have passed on to its anterior surface. The percussion note over such a liver is resonant unless the finger be firmly pressed down upon it, when the intestines are displaced and the note becomes dull. This suggests the presence of free gas in the peritoneal cavity and if there be free gas in the peritoneal cavity and a large liver of course the same phenomenon would be observed. The disappearance of the liver dulness in cases of abdominal distension from intestinal obstruction depends upon a different cause —namely, the tilting upwards of the liver so that its anterior border comes to look forward and presents too narrow a surface to yield a dull note on percussion. For this reason we have come to recognise that the disappearance of the liver dulness is an untrustworthy sign of gas in the peritoneal cavity. If it be due to rotation upwards of the liver there will still be a dull area laterally. If it depends upon gas in the peritoneal cavity this region will probably be resonant. But there is no certainty about this, as masses of lymph and collections of fluid may well give rise to dulness anywhere.

I used often to be puzzled by the different results obtained by different percussors but the different degree of pressure bestowed by a finger on which percussion is made no doubt accounts for it in part. It was also a matter of surprise that some observers could hear murmurs which were inaudible to others until I found out for myself what Dr. Ringer had previously described—namely, that pressure with the stethoscope modifies the pitch of many, if not all, murmurs and makes some entirely disappear. My own observations were first made upon those strange musical murmurs that are sometimes heard over empyemas at a long distance from the heart. Many of them are made much more high-pitched by pressure and some entirely disappear. Dr. Ringer's observations were made on ordinary heart murmurs. A heavy-headed man with a wooden stethoscope may hear nothing of a murmur which is quite startling to a light-handed man with a binaural stethoscope. One of the most striking cases of the sort was that of a right-sided empyema; the musical murmur was heard at the upper level of the dulness in front at about the level of the fourth rib and curiously enough it persisted for a long time after the cavity had closed. Another very remarkable one occupied an extensive triangular space with the apex at the spine over an enormously vascular sarcoma of the liver. The causation of these queer murmurs is, I believe, unexplained and it is equally unexplained why pressure with the stethoscope should affect them in this strange way. They are somehow produced in the thoracic wall but I have never been able to find any pathological condition to account for them, though I have sometimes had the opportunity of passing my finger through the incision I had made on to the inner surface of the chest wall at a spot where such a murmur had been heard and sometimes have proved by a post-mortem examination that no naked-eye changes were observable.

Let us now turn to the examination of a normal person. The first thing that strikes one in examining a healthy young man or boy standing up is that there is usually remarkably little resonance in the abdomen It is often impossible to percuss out the lower border of the liver with anything like certainty, the lower part of the abdomen is nearly always more or less dull, and the same may be said of the left flank. There is nearly always tympanitic resonance over the cæcum and often some over the stomach, the latter extending up over the left costal margin into the axilla, reaching as high as the sixth rib in the nipple line, but that part of the abdominal wall which corresponds to the anterior wall of the stomach is very often dull and sometimes the only resonance in front is a transverse band corresponding to the transverse colon. If the patient be placed on his face and examined from below the area of dulness is still larger, it may, indeed, be quite dull, or there may be only a faint approach to resonance at the cæcum and transverse colon. If he be placed on his back the dulness is diminished, the lower border of the liver can nearly always be determined, the anterior surface of the stomach becomes resonant, while the resonance in the left axilla is replaced by dulness, and more or less resonance is obtainable over the small intestines. These phenomena evidently depend upon the facts that in a healthy young person with a good digestion there is not much gas in the small intestines and only a moderate amount in the stomach and large intestine. Of this one has ocular demonstration in operating on properly prepared patients for, say, appendicectomy or gastro-enterostomy. The fluid or semi-solid contents gravitate downwards and hence the dulness caused by the lower part of the stomach becomes continuous with that of the liver in the erect posture and even the cæcum and transverse colon may yield a dull note when the patient is placed upon his face. Of course, these observations do not apply to overfed dyspeptic people above middle age who pass for healthy and even in those I am describing the conditions vary enormously from time to time. The moral is that it is useless to attempt to percuss out the solid viscera while the patient is standing upright.

It was long ago observed that in cases of intestinal obstruction with much distension it is impossible to say whether or not there is free fluid in the peritoneal cavity because the flanks may be dull when the patient is lying on the back but resonant in the uppermost flank when he is placed upon his side. This has been explained either by supposing that if it be a large intestine obstruction the colon is distended partly by gas and partly by fluid contents and the fluid gravitates to the lowest part, or in cases of small intestine obstruction that coils of small intestine loaded with fluid contents sag over and replace those which are distended with gas.

It is at first rather surprising to find that the upper limit of the dull area corresponding to the liver and the heart in front is almost exactly the same in the erect position and in dorsal decumbency; in other words, the liver does not fall away much from the front when the patient stands up. When he lies on the face and the dulness is percussed from below it *is found to be only a very little higher*, the change being not nearly so great as when the dulness in the back is percussed in the erect and in the knee-elbow position. This, however, becomes more easy to understand when we remember that the anterior part of the diaphragm is directed much more horizontally from its origin than the posterior which is practically perpendicular for a considerable distance, as is shown in vertical sagittal sections of the trunk; in other words, the pleural sinus hardly exists in front, whereas behind there is a considerable space only occupied by the lung during deep inspiration in the erect posture but which is easily opened up for the admission of the lung by the falling away of the liver when the patient lies on his face or assumes the knee-elbow position. When he lies on his back and is percussed from below both flanks are usually quite dull, whereas, as has been said, when he is placed in the knee-elbow position or lying on his face both flanks are usually more or less resonant and it will not be forgotten there is often very little liver dulness and sometimes none at all.

Some normal individuals experience discomfort when lying on the left side because they feel the heart beating against a part of the chest with which it is not in contact in the erect posture or in dorsal or right decumbency. That the heart does sag over to the left in left decumbency may be ascertained in thin persons by the displacement of the maximum apex beat, and I have satisfied myself that the dulness also extends further to the left; but it is not easy to estimate the exact amount in the particular individuals I examined. The dulness caused by the spleen and the left kidney in the left side of the back are greatest in dorsal decumbency and least in ventral decumbency or the knee-elbow position. From what has been said it will be seen that dulness which shifts with changes in position is the normal condition at both bases behind and is no proof of the existence of fluid in the pleura.

I do not know that there are any more practical deductions to be drawn from these observations than those which have been already referred to. I therefore now pass on to some more pathological conditions. I have already dealt with hydrothorax and empyema by stating that in the former the dulness shifts at all events much less than was formerly supposed if it shifts at all and in the latter it practically never shifts when the collection occupies the general pleural cavity and certainly never shifts at all when the empyema is localised. It is quite otherwise in cases of hydropneumothorax and pyopneumothorax. Here the fluid moves about quite freely like water in a half-filled bottle and the dulness shifts in consequence of the movement when the position of the body is changed. The only practical point [illegible] these con- [illegible] position [illegible] fluid and not to push it in too far lest it should pass through the fluid into the gas beyond. If proper precautions have been taken as to the position of the patient and still no fluid comes into the bottle the needle should be slowly withdrawn and should not be removed suddenly. This process of gradual withdrawal must be continued until the end of the operation if the last few drops of fluid are to be removed. It may be added that there is more hope of removal of all the fluid if air be present than if it be a case of simple pleurisy with effusion or empyema.

Everyone knows that the dulness in a case of ascites does not by any means always assume the horse-shoe shape which is described as typical. I have not had the opportunity since I began to prepare this lecture of examining many cases but I present to you diagrams of a few. In each case I have shown the modifications which occurred when the patients were placed in dorsal or lateral decumbency, but I did not venture to place any of these unwieldy people on my high couch. It will be seen that none of them corresponded to the normal type and that the most common deviation from it was that there was resonance in the right inguinal region. This resonance [illegible] cæcum, not I suppose b[illegible] part of the intestine, [illegible] ted to favour its submergence beneath the fluid; it must, I think, depend upon the fact that this part of the bowel is generally the most distended with gas. The line of the transverse colon comes out in all and the stomach may cause a prolongation of the central resonance into the left hypochondrium.

*It is not my purpose, even if I had made sufficient observa*tion to enable me to do so, to say what is the most usual shape for the dulness of a simple ascites to assume but I desire to point out that a departure from the so-called typical horse-shoe shape does not prove that the fluid is loculated or necessarily suggest the presence of peritoneal adhesions. The real test is whether the dulness shifts on changing the position of the body or not; in the case of general ascites this takes place with great rapidity, in that of localised collections of fluid not at all or very slowly. It is, of course, presupposed that the existence of fluid has been proved, say, by the presence of the sense of fluctuation. If called upon to tap an ascitic abdomen in which the dulness is irregular and does not shift it is unwise to employ the simple trocar or an aspirator because there is nothing to indicate the thickness of the layer of fluid which causes the dull note. The right plan is to make a small incision through the abdominal wall, as may be painlessly done with the help of local anæsthesia, and to close the opening with a stitch when the fluid has escaped.

Another condition in which the dulness is not so marked a feature as the resonance but in which it shifts with great rapidity is that in which a perforation of a gastric or intestinal ulcer has led to the accumulation of gas and fluid in the peritoneal cavity. Nowadays, these cases are usually diagnosed early and submitted to an operation, or if not the patient dies before the characteristic signs have developed. But sometimes they become subacute and a huge cavity is formed containing pus and gas, of which the posterior wall is formed by the abdominal viscera all matted together by lymph and the anterior wall by the abdominal and thoracic parietes. This condition, which has been called subdiaphragmatic pneumothorax, may give rise to difficulties in diagnosis because the accumulation of gas may press the diaphragm upwards so high that the physical signs in the chest are typically those of pneumothorax—absence of breath sound, bell note, &c. I have seen the tympanitic note extend as high as the second rib in front. A mistake should not, however, be possible because the tympanitic note and bell sound are continuous and the same over the whole extent of the cavity and the liver dulness has absolutely disappeared. But an investigation of the effect of turning the patient on the side should not be omitted. It may always be done without risk and it will be found that a part of the tympanitic area instantly becomes dull, the amount depending upon the quantity of pus that has accumulated. I have observed in one case lately, a ruptured typhoid ulcer, that vocal fremitus was to be felt very distinctly all over the abdomen and even over the iliac bones. The patient was a thin man with a deep voice. I do not know whether this is a characteristic sign but it will be interesting to see if it is met with in other cases.

This leads up to the subject of localised peritoneal abscesses containing gas which *so commonly result from* appendicitis and which unfortunately often lead to postponement of the operation. The presence of gas makes it impossible to feel a lump and if a swelling has been present before any considerable amount of gas has accumulated its disappearance may be welcomed as the sign of an improvement which does not exist. I remember many years ago, before we were so well acquainted with this disease, a stout old lady in whom we watched the appearance and disappearance of the lump and hoped, in spite of the persistence of fever, that the mischief was subsiding, whereas really the abscess was tracking up under the diaphragm which it ultimately perforated and this, curiously enough, was followed by acute tuberculosis of the right lung. I do not wish to encourage you to sit the patient up and to examine his back in such circumstances, because there are certain, though perhaps slight, risks in doing so, but it is most probable that in the sitting posture the right lumbar region will become markedly tympanitic while the right iliac fossa will become dull, though in the recumbent position the iliac fossa may be resonant and the flank dull.

A PECULIAR FORM OF CHRONIC HYPERPLASIA OF THE MUCOUS MEMBRANES OF THE UPPER RESPIRATORY TRACT.

BY SIR FELIX SEMON, C.V.O., M.D. BERLIN, F.R.C.P. LOND.,
PHYSICIAN-EXTRAORDINARY TO HIS MAJESTY THE KING.

VERY many years ago I observed a curious case of chronic hyperplasia of the mucous membranes of the pharynx and larynx of which unfortunately, in spite of much searching, I have not been able to find my notes. But the impression left by it upon my mind was such that I can even now, I think, faithfully remember its salient features. It was the case of a lady, about 30 years of age, the wife of a medical practitioner. She consulted me on account of general discomfort in her throat and of considerable difficulty in swallowing, which had, when I saw her, already lasted for many months, whilst her general health had not suffered. The aspect of her pharynx and larynx was such as I had never seen before. The whole of the soft palate, including the arches and the uvula, the posterior wall of the pharynx, the epiglottis, the aryteno-epiglottic folds, and the arytenoid cartilages were uniformly thickened and presented a peculiar yellowish, shiny, somewhat gelatinous-looking appearance, which reminded one of nothing so much as of the aspect of a lardaceous kidney. The infiltration was markedly smooth, the mobility of the arytenoid cartilages was unimpaired but that of the soft palate seemed to be rather slack, a circumstance easily enough accounted for by the general and considerable infiltration. I first of all thought that I had to do with a case of tuberculous pseudo-œdematous infiltration, but there were no other signs of tuberculosis anywhere and the condition showed no tendency towards a destructive metamorphosis. I kept the patient under periodical observation for nearly two years, during which no method of treatment was of any avail. I was therefore not a little surprised when about two years afterwards she again called on me to show me that there had been a return to perfectly normal conditions. There was as little obvious cause for restoration to health as there had been for the orginal affection.

The second case occurred in a woman, aged about 40 years, whom I only saw once. In that case the conditions were similar to those observed in the first but much less developed.

My third case was shown on Nov. 7th, 1902, to the Laryngological Society of London and has been described in its Transactions as follows :—

> The patient was first seen on July 12th of the present year with a history of long-standing throat trouble and occasional difficulty in swallowing. She had been seen by various medical men, all of whom,
> a affection as rather
> s e of it.
> of the uvula was
> he uvula and the adjacent parts of the soft
> nfiltrated and at the same time quite smooth
> the most characteristic point consisted in the

> appearance
> lardaceous degeneration. In the la
>
> transparent than its fellow, it had a s
> arytenoid.
>
> There was no evidence of kidney trouble but on examination of the legs there was slight pitting on pressure, particularly over the external malleoli.
>
> Her voice was normal. There was no pain and no difficulty in breathing. The organs of the chest were normal.
>
> The urine was examined later and found perfectly normal. On July 14th, 1902, the local condition of both pharynx and larynx was much better than three days previously. The patient was given an arsenic and iron mixture.
>
> On July 29th, 1902, the swelling both of the uvula and of the right arytenoid cartilage was much more marked than on the occasion of her last visit and the colour was much more that characteristic lardaceous yellow which had
> examination. The condition

>
> than they were in July.

n these three cases and observed that I was not aware that the condition had ever been described. The case excited a good deal of interest as none of those present had ever seen anything similar. It was suggested that a piece of the uvula should be removed for microscopic examination, and the patient having consented to this, I amputated a part of the uvula and submitted it to Mr. S. G. Shattock, pathological curator of the Royal College of Surgeons of England, who has kindly favoured me with a full description of the histological characteristics of the infiltration. Before giving this in his own words I may state that the patient shortly after the little operation left London and that I have not since heard from her. The following is Mr. Shattock's description :—

> The uvula is generally enlarged, its cross section having a diameter of 9 m.m. and its length being correspondingly increased. The investing epithelium is everywhere intact and normal; between its elements a few polymorphonuclear leucocytes have wandered from the subjacent tissue. The increase in size is due to a diffuse formation of finely fibrillar connective tissue, in the central part of which there occur small groups of fat cells. The proper corpuscles of the new connective tissue have the usual characters and are moderate in number. The uniformity of the microscopic picture is only broken

FIG. 1.

vessels.

At the time when I demonstrated these cases I considered, as already stated, my observations as unique. Shortly afterwards, however, I found that 18 months previously Dr. A. Brown Kelly of Glasgow had given a very excellent description of a similar case in THE LANCET of April 6th, 1901, p. 995, under the title "Sclerotic Hyperplasia of the Pharynx and Naso-pharynx." *In his case the* patient was a man, aged 34 years, who for about eight years had been subject to slight attacks of sore-throat. Three years before Dr. Brown Kelly saw him he began to feel something in the pharynx which he wished to expel. These sensations had gradually increased. Latterly severe choking fits had been excited and nasal respiration had been *partially obstructed for a year. On examination his* pharynx presented a very striking appearance. The uvula was very large and hung like a curtain concealing the posterior pharyngeal wall. Its length was over one and
thick-
were
d the
lding
ed a
peculiar aspect. A narrow tract of abnormal tissue ran to the middle of the posterior wall. On each side of this, extending outwards to the lateral wall and incorporating with it a part of the right and the whole of the left faucial pillar, was a broad prominent band which was thickened in its outer part. These bands passed upwards into the naso-pharynx and downwards to the upper end of the œsophagus. Their consistency was that of muscle and they could be pushed *en masse* towards the middle line. Their colour was a uniform grey and their surface was perfectly smooth. The appearance of the naso-pharynx revealed marked changes. The lumen of the cavity was reduced so as barely to admit the forefinger. Only a small part of the septum and middle turbinates could be seen, the coronal arches and Eustachian orifices were concealed. aso-
pharynx, like those in th and
firm. The bands on the were
seen to pass downwards the
sides of the epiglottis t nds.
Within the next two years no change was noted in the conditions described with one exception. The patient in October, 1900, complained of sore-throat. When Dr. Brown Kelly saw him on the sixth day of the attack the pain, which was confined to the left side, had begun to subside. There was then great swelling of the left band, especially about the level of the epiglottis. Its surface was smooth and pale. Three weeks *later the œdema had diminished* considerably so that a view of the larynx was obtainable. It was then found that the movements of the left arytenoid during phonation produced a clicking sound owing to its coming into contact with the overlapping tissues. Five months after the acute attack the left band continued thicker than the right and the clicking sound was still heard.

Dr. Brown Kelly, shortly after the patient came under his observation, removed the uvula by means of the galvano-caustic snare, since which time the choking attacks ceased and the patient considered himself practically cured. A piece of the removed uvula was preserved in absolute alcohol and a very full account of its minute structures is given in the paper by Dr. A. R. Ferguson, senior assistant to the professor of pathology of the University of Glasgow. (It ought to be mentioned that the macroscopic and microscopic conditions observed are very fully illustrated in Dr. Brown Kelly's paper.) The report of the pathologist, for the details of which those interested must be referred to the original, is thus summed up in his own words:—

In the concluding part of his paper Dr. Brown Kelly exhaustively discusses the question of the nature of the affection from a clinical point of view and excludes rhino-scleroma, tertiary syphilis, and hereditary syphilis. Whilst he is unable to define the disease of which the condition observed by him is a manifestation, he points out that an analogous condition probably exists in subglottic hypertrophic laryngitis and admits that in the hyperplastic variety of hereditary syphilis the histological appearances closely resemble those of the affection described by him under the name of "sclerotic hyperplasia of the pharynx and naso-pharynx."

An apparently similar case was shown under the name of "Chronic Œdema of the Larynx (?) Amyloid" to the Laryngological Society of London on Feb. 6th, 1903, by Dr. J. Dundas Grant, in which the larynx was the seat of a pale, somewhat solid, œdema of the epiglottis, and both aryepiglottic folds, especially the left, and the palate and pillars of the fauces, especially the left one, were somewhat thickened. Inasmuch, however, as Dr. Dundas Grant on Feb. 5th, 1904, showed the patient again, who meanwhile had greatly improved under antispecific treatment, he himself admitted that the case had probably been one of
no evidence either direct or
the subsequent discussion,

sented some clinical resemblances to the cases so far described, probably does not belong to the category under discussion as sections of the enlarged epiglottis which was removed showed numerous roundish nodules deep under the mucous membrane which strongly resembled, but were not characteristic of, tubercle.

Another case as to which it is extremely doubtful whether it is of the same nature as those described by Dr. Brown Kelly and myself was shown by Dr. A. Logan Turner to the Laryngological Society of London on Jan. 15th, 1904. He described it as an "œdematous infiltration of the uvula, left half of the soft palate, and left lateral wall of the pharynx, *infiltration of epiglottis* and both arytenoid regions." In that case the onset of the disease was apparently quite sudden. Serious respiratory symptoms developed within three days and on the evening of the third day tracheotomy became necessary. The original diagnosis was acute septic infection of the pharynx and larynx. At that time the uvula and soft palate were œdematous and the epiglottis was markedly swollen *and rigid*, reddish, and curved back. Both arytenoid regions
be obtained of the interior,
the tracheal tube could be
he local appearances were
d at the time of the acute
attack with the absence, however, of the acute inflammatory signs. Again, two months later, after administration of antisyphilitic treatment the local condition was very much the same as previously seen but in addition the left lateral wall of the pharynx had become swollen and presented an appearance similar to that of the soft palate. A small piece of tissue was removed from the infiltration on the
microscopic sections of this
tuberculosis or malignancy.
were œdematous, the blood-
vessels (arterial and venous) were much engorged, and there

were areas of small-cell infiltration. The appearance suggested somewhat the existence of lymphatic obstruction." In conclusion, Dr. Logan Turner stated that it was impossible to say definitely whether the present condition dated from the acute illness or whether that was merely superimposed upon a chronic infiltration such as at present existed.

In the discussion Dr. P. McBride, who had seen the patient in consultation, observed that it seemed to him that the case must be either specific or some form of infiltration associated with obstruction of the lymphatics the nature of which he was unable to recognise. I observed that I could not agree that this case was very similar to my own and that, as a matter of fact, unless Dr. Logan Turner had mentioned the connexion, the thought of my own cases would have hardly occurred to me. The uvula certainly had a somewhat infiltrated aspect and was yellowish in colour and a similar condition, although in a minor degree, was to be seen on the epiglottis but there were not nearly so much infiltration and peculiar yellowish colour as in my own case. What differentiated this case more particularly from my own was that the infiltration was not nearly so universal. If the explanation of the case lay in its being due to some particular obstruction of the lymphatics, the infiltration should be more general. I was not prepared to give an opinion as to the nature of this case.

Dr. Dundas Grant said that he had under his care a case somewhat resembling this but very chronic in its course. He had shown it to Dr. Hajek, who thought it extremely rare and had only seen one or two cases. In his opinion it was a kind of lymphadenoma which was due in reality to infiltration of small cells. The society was now getting a considerable collection of these cases of what might roughly be called "chronic œdema." In one case which he had shown to the society an improvement was taking place under mercurial inunctions and it was probably tertiary syphilis. Other cases which had been reported turned out to be tuberculous. It would be interesting if the after-history of these cases could be brought before them.

In reply Dr. Logan Turner said that he would certainly keep the patient under observation and if any definite diagnosis was arrived at he would let the society know. The microscopic sections revealed practically nothing. The connective-tissue spaces were somewhat loose and œdematous, the blood-vessels were a little thickened here and there, and round about them there was a certain amount of small cell infiltration, but there was nothing very definite as regards the question of tuberculosis. Looking at the laryngeal condition the pale œdematous infiltration of the arytenoids was certainly suggestive.

Remarks.—The above list comprises seven cases, which have been shown before, or mentioned at, the London Laryngological Society in the course of the last three sessions as forming a group of their own and constituting a hitherto apparently undescribed form of chronic hyperplasia of the mucous membranes of the naso-pharynx, pharynx, and larynx. From this group, however, I think that the cases of Dr. Dundas Grant, Dr. Lambert Lack, and Dr. Logan Turner must be eliminated, as in all probability, although there was some similarity in the clinical appearances, the cause of the peculiar swelling in these cases was tuberculosis, syphilis, or acute septic infection. Four cases only would therefore remain, Dr. Brown Kelly's and my own three, and as one of the latter was only seen once by me, it is of practically no value for the decision of the nature of these cases. The more important, however, are the three remaining ones: Dr. Brown Kelly's case, my first case, and my third case. The microscopic appearances in Dr. Brown Kelly's case and my own third case are practically identical. It is, indeed, remarkable how much the findings and conclusions of Mr. Shattock's report tally with those of Dr. Ferguson, considering the fact that Mr. Shattock's report was written in ignorance of Dr. Brown Kelly's case and that he only became acquainted through me with Dr. Ferguson's report after he had delivered to me his own description of the microscopic appearances seen in my own case and the conclusions he had derived therefrom. Full and excellent, however, as both these reports are, they unfortunately throw no more light upon the etiology of these curious cases than long-continued clinical observation. All that can be said is that we have to do with a chronic hyperplasia of the tissues involved and not associated, so far as can be judged so far, with the presence of any specific micro-organism. Tuberculosis, syphilis, and rhino-scleroma seem to be quite out of the question in them all.

On the difficult question raised by Dr. Brown Kelly—viz., whether the affection observed by him and me is analogous in nature to subglottic hypertrophic laryngitis—I wish to speak with all possible caution. I will not venture to say more than that the same reason, which induces me to think that the name given by him to the new affection—viz., "sclerotic" hyperplasia—is not happily chosen, combats also against my believing in its identity or analogy with hypertrophic subglottic laryngitis. In all probability Dr. Brown Kelly was led to adopt the term "sclerotic" through the conclusion at which his microscopist arrived—viz., that the condition represented a "chronic hyperplasia of the interstitial tissues of the parts involved of apparently progressive character with no tendency towards degeneration." This characterisation, if correct in every detail, would indeed be analogous to the condition known as hypertrophic subglottic laryngitis, Stoerk's blennorrhœa, or scleroma of the larynx and would quite justify the use of the adjective "sclerotic," which in a medical mind is more or less associated with the conception of a progressive interstitial change incapable of spontaneous or remedial repair.

I hope that I shall not be considered captious if against this view, which assumes the pathology of the new affection to be one of progressive, mostly interstitial, hyperplasia, I urge the all-important fact that in my own first case a spontaneous complete disappearance of the infiltration took place after it had existed for several years and that in Dr. Brown Kelly's own case a change for the better had taken place when last he saw his patient. These facts appear to me so irreconcilable with the idea of the change being of a genuinely sclerotic character that I venture to propose, instead of the expression "sclerotic" hyperplasia, the non-committing name of chronic hyperplasia, which may do service until we have learnt to understand better the nature of the curious affection described in this paper.

Wimpole-street, W.

PNEUMONIA WITH INFECTIVE ENDOCARDITIS AND MENINGITIS.

BY DONALD M. LIVINGSTONE, M.B. GLASG.,
LATE SENIOR ASSISTANT MEDICAL OFFICER, BARNHILL HOSPITAL, GLASGOW;
AND
ARCHIBALD JUBB, M.D. GLASG.,
LATE JUNIOR ASSISTANT MEDICAL OFFICER, BARNHILL HOSPITAL, GLASGOW.

CASES of pneumonia with endocarditis and meningitis as complications or sequelæ have been often recorded, yet in few of these instances have the symptoms been so manifest as to permit an easy diagnosis during life. The literature of the condition is of comparatively recent date and until Osler, in 1885, by his Goulstonian lectures, proved the unsuspected frequency of ulcerative endocarditis and meningitis, one or both, following pneumonia, the subject had not received much attention. Indeed, Osler[1] states that the committee for collective investigation in its report of 1000 cases of pneumonia mentions infective endocarditis only once. Since then it has been studied by numerous observers and the importance of pneumonia as a causal factor is made evident by Kanthack's statistics in which 14·2 per cent. of all cases of infective endocarditis showed an antecedent pneumonia. The following instance of the double complication has been considered by us sufficiently notable to deserve publication.

A man, aged 40 years, was admitted into Barnhill Parochial Hospital on Feb. 25th, 1902, suffering from pneumonia of the right apex. The date was the fifth day of the disease. There was no delirium and the other organs appeared to be normal. The only conspicuous feature was the occurrence on the fifth and sixth days of sharp pleuritic pain which was controlled by hypodermic injections of morphine. The crisis took place on the ninth day and for three days thereafter the patient was apparently convalescent. On the thirteenth day, however, the temperature, which had not exceeded 99° F. for four days, rose to 102° and the patient became restless. On the succeeding four days the temperature rose and fell daily, the highest reading being 102° and the lowest 98 4° He slept little, perspired heavily, and complained of pain in the præcordial region On the eighteenth day the calves of the legs were painful and tender He cried out when they were pinched even slightly. On the following day he had a rigor and the temperature rose to 103 2° With the exception of the pain in the legs he was easier on the next two days, the morning temperatures being 100° and the evening ones 103 8° and 104 2° respectively At this time the first sound of the heart was noticed to be distinctly impure There was a soft systolic murmur heard only at the apex The cardiac dulness was normal He passed a restless night and on the twenty-second day was still restless, with persistent sickness and vomiting and slight delirium The temperature rose to 105° and he complained of severe headache Next day the headache was still distressing and he vomited frequently The pupils reacted to light and in accommodation and there was no optic neuritis On the following day he was very restless and delirious at intervals On the twenty fifth day he had two general convulsive seizures, the delirium was continuous, and he was extremely restless On the next day his condition was much the same, cough was troublesome, and the bowels were loose There was a considerable quantity of râles in the lungs and the respirations attained a frequency of 66 whilst the pulse was only 104 He died on the twenty seventh day of the illness There was no rash or strabismus at any time

---

[1] Goulstonian Lectures. THE LANCET, March 7th (p. 415), 14th (p. 459), and 21st, 1885 (p. 505).

At the necropsy the upper lobe of the right lung was grey on section, somewhat soft, and showed only a moderate degree of resolution The pericardium contained two ounces of yellowish serum The heart was of ordinary size, rather pale in colour, and the walls were of normal thickness On the auricular surface of the mitral right cusp was found a circular clump of granulations nine millimetres in diameter and four millimetres high and part of its edge was over the line of contact Exactly opposite, on the other curtain, was a similar but smaller growth measuring seven millimetres in diameter and projecting three millimetres above the valve surface The vegetations came into apposition when the valve was closed The tissue round the vegetations was thickened and œdematous but there was no defect elsewhere The other valves were normal Examination of the brain revealed a diffuse purulent meningitis, the pus was thick and much more abundant on the cortical surface than at the base The other organs seemed healthy, with the exception of the spleen which was somewhat enlarged Sections of the valvular granulations cut in paraffin showed, besides masses of cocci many diplococci resembling Fraenkel's pneumococcus Unfortunately the brain was destroyed before smears of the pus could be taken

Some points in the case merit notice The brief period of apparent convalescence was marked enough to show that the pneumonia had waned and this was confirmed at the section by the fact that the lung had partially resolved Further, the patient was able to indicate his new discomfort in the cardiac region He perspired heavily, as recorded in the daily note "Sweating is a very frequent symptom (of malignant endocarditis) and is usually of special notice from the peculiarly drenching character which is second only to ague and usually far beyond the average mark of phthisis and pyæmia " [2] The cardiac sounds at this time were clear, no impurity being detected until the twenty first day of the illness No presystolic element was ever audible and the size of the valvular growths could not be considered sufficient to cause an appreciable degree of stenosis, whilst their position was such as to allow a moderate amount of regurgitation The pain and tenderness in the calves of the legs were taken to be the first signs of meningitis Leube[3] lays stress on the hyperæsthesia of the skin and muscles, especially of the legs and calves On the nineteenth day the patient had the only rigor which occurred during the illness From the evening of the twenty first day the third and last stage of the illness was established, dominated almost wholly by the meningeal symptoms During the last few days the cardiac murmur ceased to be audible The chart which was kept four hourly, showed the [illegible] with the præcordial pain as the first expression of [illegible] hœa was probably due to minute embolic infection of the intestines, though these appeared normal to naked eye inspection

Our combined record of pneumonia in Barnhill Hospital for 20 months reached the total of 235 and the above is the only case in which the double complication of infective endocarditis and meningitis was observed Pye Smith[4] records 435 cases of pneumonia, with seven of ulcerative endocarditis, five of meningitis, and three of both Osler[5] records the double complication five times in 103 necropsies The discrepancy between the figures of the two authors is possibly due in the first place to the fact that Osler's record is a pathological one exclusively and in the second place to the difficulty of recognising the complication during life When the heart or brain is involved in the acute stage of pneumonia the recognition of the new infection is a business of unusual perplexity and especially so if both be affected, for then owing to the commanding nature of the meningeal symptoms and the possible latency of the cardiac ones, the former may completely overshadow the latter

One case of meningitis alone occurred in our record, the patient was a girl, aged 16 years, and she died on the seventh day of the illness One case of infective endocarditis alone was observed, there was a double aortic murmur—the pneumonia in this case was also in the right apex—and the aortic valve was found perforated and covered with recent vegetations There was here a probability of former cardiac disease Glynn,[6] quoting Orth, states that infective endocarditis is never found save in old valvular disease, but in our detailed case there was not the slightest suggestion that the endocarditis had been grafted on a previous lesion Kanthack[7] found chronic disease of the valves in 64 per cent and Kelynack[8] recognised old cardiac lesions in 75 per cent but says "In only four instances were there satisfactory grounds for believing that the valves were normal prior to the establishment of the infective process

In conclusion we express our thanks to Dr William Core, superintendent of Stobhill Hospital, late medical superintendent of Barnhill Hospital, for his courtesy in permitting us to publish this case

A CASE OF ACUTE SEPTICÆMIA TREATED WITH ANTISTREPTOCOCCIC SERUM, RECOVERY[1]

BY G H CRESSEY, M R C S ENG , L R C P LOND

THE patient, aged 15 years, a visitor to Torquay, had always been a perfectly healthy girl Ten days before I saw her, while paddling in a stream, she cut the plantar surface of her right great toe, which bled freely but caused her no further trouble and she went to Torquay I was called to see her late in the evening of August 10th, 1904 and was told that after spending a restless night she had been feverish and delirious all day Her temperature was 103°F and her pulse was 110 Her tongue and her breath were foul but no mention was made of any injury till the following day when I was asked to look at her foot I then found a nasty looking blister over the ball of the right great toe, an erysipelatous blush over the tibia and tenderness in the ham and inguinal regions A free incision was made [illegible] escaped a large [illegible] en relieved, her [illegible] 100 She was given quinine and iron and put on a beef tea and milk diet On August 14th Dr W Stabb saw her with me and the quinine was increased and the iron was omitted On the 15th her temperature was 104° and her pulse was 120 There were considerable swelling over the dorsum of the foot increased blush and also swelling over the tibia Dr Stabb again saw her with me and under chloroform free incisions were made over the foot and the leg In the evening the temperature had declined to 101 4°, the pulse was 104 and the respirations were 24 During the day she had had five grains of quinine On the 16th the leg was placed in a 1 in 80 carbolic acid bath and as the temperature ranged from 102·8° to 105° she was given five grains of quinine and also two drachms of brandy every four hours. There was a slight cough but nothing pointing to lung trouble. The pulse was 114 and the respirations were 24. She had had a fair night and had taken her nourishment well. On the 17th she had been delirious during the night but there were no increase of redness and no tenderness in the ham or the groin. The temperature ranged from 101·8° to 103·3° and the pulse was 106. The leg was placed in a chloride of sodium bath, 1 in 12, and she had during the day four grains of salol every four hours. On the 18th she was delirions during the night and perspired freely towards morning. On account of the urine being dusky with a slight trace of albumin the salol was stopped but the brandy was increased to three drachms every four hours. At noon the temperature was 104·6° and 20 cubic centimetres of antistreptococcic serum, obtained from the Lister Institute, were given hypodermically at 4 P.M. At 5.30 P.M. the temperature had fallen to 101·1°. On the 19th, after a restless night, ten cubic centimetres of the serum were injected at 4 A.M., after which the patient slept. There was a troublesome cough and a well-marked systolic apical bruit had developed, but there were no morbid sounds over the lungs. She was given digitalis and carbonate of ammonium every four hours and another injection of the serum. The temperature ranged from 101·8° to 104·8°. The patient continued in much this state till the 24th when her temperature fell to 99·8° during the night but it rose to 105° in the afternoon, the patient having had a slight rigor at 9.30 A.M. The cough was troublesome but there were no abnormal lung sounds. She was given three grains of quinine and five minims of solution of strychnine three times daily. She continued in much the same state for the next eight days though the noon temperature never rose quite so high. The cough was troublesome but there were no expectoration and no morbid lung sounds and the respirations only once reached as high as 30. After the 31st no more serum was used. A swelling appeared over the outer side of the right knee. The temperature fell to normal on Sept. 3rd and was subnormal up to the 6th. On the 7th the swelling over the knee and another over the ankle were incised, letting out some inodorous pus. The patient afterwards had a disturbed night and her temperature rose from 101° to 105·8° in the evening, her pulse from 120 to 140, and her respirations from 22 to 48. She was given ten cubic centimetres of serum, after which there was a profound rigor lasting nearly an hour, followed by profuse sweats and the temperature gradually fell to 96·8° at 7 A.M. on the 9th but rose to 104° in the evening, the respirations being 33. On the 10th there were physical signs of pneumonia over the right base. On the 15th the temperature reached 105°, there was stabbing pain in the right side of the chest, and a pleuritic rub was heard. Three leeches were applied with great relief. On the 19th there were physical signs of effusion and on the 28th there was dulness up to the middle of the scapula and the apex beat was displaced to one and a half inches outside the nipple line. On Oct. 2nd, after aspirating a syringeful of thin watery-looking pus, Dr. Stabb resected about one and a half inches of the seventh rib, letting out about three pints of curdy, inoffensive pus and inserted a large drainage tube. The temperature at once fell and on the 14th the tube was finally removed and the patient rapidly convalesced, still, however, having the systolic apical bruit and a rapid pulse. Altogether 235 cubic centimetres of the antistreptococcic serum had been injected. The patient had several superficial abscesses, due apparently to the serum, but not as a rule at the site of the injections.

[8] Quoted by Glynn *supra*

[1] A paper read before the Torquay Medical Society on Jan 18th 1905

I think that this most instructive case may be divided into three stages. 1. The stage of acute sepsis, during which there was lymphatic poisoning with swollen glands, high temperature, and rapid pulse. During this period the antistreptococcic serum was used pretty regularly until the skin became exquisitely tender. 2. The formation of superficial abscesses, nearly all of them being immediately beneath the skin. During this stage the great vital organs remained practically unaffected until a pleuro-pneumonia appeared in the right lung. 3. The formation of an empyema, the operation of paracentesis thoracis with marvellously rapid result, followed by convalescence in which there were no drawbacks.

Torquay.

MENTAL SYMPTOMS ASSOCIATED WITH HEART DISEASE.

BY H. KERR, M.A., M.D. GLASG.,
ASSISTANT MEDICAL OFFICER, BUCKS COUNTY ASYLUM.

THE presence of mental symptoms in cases of heart disease is not unusual; on the contrary, in all cases of grave heart disease one expects to find at some period or other the mental condition of the patient to vary from the normal standard, although only in a few would the symptoms justify the classing of the patient as insane. The frequency of heart disease in the insane may be estimated from the statistics of the reports of the Commissioners in Lunacy and in the report for 1902 the death-rate from this cause is found to be 10·07 per cent. of all causes of death. In a large proportion of these cases the heart affection had in all probability but little direct relation to the mental condition of the patient but in a certain number of cases mental symptoms are present which have a very definite relation to the cardiac condition and conform to a certain clinical type. It is this fact which has led alienists to give a place in their classifications to the insanity of heart disease as a distinct clinical variety, with subvarieties according to the different cardiac lesions.[1] The following case is of peculiar interest, not only on account of the mental symptoms which are characteristic of this type of insanity and which, judging by their sequence in the history of the case, may be fairly ascribed to the heart affection but also on account of the extreme degree of hypertrophy of the heart which was found to be present.

The patient, a man, aged 52 years, married, was admitted to the Bucks County Asylum on Feb. 6th, 1901, suffering from a first attack of insanity of three months' duration. He was a blacksmith and had been in failing health for about a year with symptoms of heart disease and failing action of the heart. There was no history of rheumatism and his general health had been uniformly good until his present illness. A month before admission to the asylum he had been received into the Hemel Hempstead Infirmary but had been sent home after nine days on account of his mental state. He had been depressed and low-spirited, with suicidal tendency, and according to the medical certificate "he told his son that he did not care anything about him or he should have him locked up or sent to the asylum, as he was afraid he should make away with himself." He had hereditary predisposition to insanity, his father's brother having been insane for many years and being at present an inmate in the Bucks County Asylum.

On admission the patient was worried and anxious in appearance and was very miserable and depressed, despairing about himself and his condition. He was suspicious of those around him and imagined they wished to injure him in various ways. He was somewhat slow and dull and disinclined to talk. Physically he was very stout, weighed 17 stones, was flabby in appearance, pallid, and looked ill; his respiration was slightly increased in frequency and dyspnœa was present, much increased on exertion, and he complained of a "sinking feeling in the stomach." Cardiac dulness was found to be much increased in every direction and marked pulsation was present over the cardiac area. A loud, blowing systolic murmur was present, heard all over the heart region but loudest over the aortic area. The pulse, 72 per minute, was regular in force and rhythm, and in character somewhat approaching the "water-hammer" type. He had slight cough and bronchial catarrh but no marked physical signs were present in the lungs. There was no anasarca and the urine was normal. He was kept in bed and under treatment with rest and cardiac tonics his general condition so far improved that in six weeks he was able to do light garden work without any ill-effects. His mental condition at the same time improved and he became cheerful and sociable, taking part in indoor games. He continued fairly well throughout the summer and the mental symptoms were not at any time prominent. In the latter part of the year the symptoms of heart disease again became very pronounced and he was quite incapacitated for work. In January, 1902, he became so ill that he had to stay in bed;

---

[1] Tuke's Dictionary of Psychological Medicine, p. 177.

anasarca appeared and became general, albumin was present in the urine, and the respiration became embarrassed with marked orthopnœa present With the failure of his bodily health and the greater urgency of the cardiac symptoms he relapsed into his previous mental condition eventually towards the end becoming very dull and stupid and dirty in his habits No improvement in his condition resulted from treatment and he died on March 18th 1902

On post mortem examination the heart was found to be enormously hypertrophied weighing 31¾ ounces The hypertrophy was general the normal shape of the heart being fairly well preserved, the muscle was soft and friable The aortic valve was incompetent, the flaps showing atheromatous change and one of them having numerous large vegetations The mitral valve was dilated and atheromatous degeneration was present which condition was also present in the aorta The lungs were heavy and œdematous and several recent infarctions were found, infarcts were also present in the spleen and the kidneys

Cases have been recorded where the heart has reached a degree of enlargement greater than in the present case, [illegible] however, be comparatively [illegible] The sequence of events [illegible] to be that hypertrophy, probably induced by his occupation had existed and been increasing for years, that the supervention of atheroma and valvular disease caused a further large increase in the muscle of the heart, that this was followed by the degeneration of muscle and failing compensation which brought in its train all the symptoms of cardiac failure To these were added the mental symptoms which were a prominent feature of the case

Stone Aylesbury

PROPERITONEAL OR ABDOMINAL HYDROCELE

By J LEWTAS, M D Lond, M R C S Eng,
LIEUTENANT COLONEL, INDIAN MEDICAL SERVICE SURGEON TO THE MAYO HOSPITAL AND TO THE EYE INFIRMARY CALCUTTA

THE descriptions of abdominal hydrocele given in English text books of surgery are so meagre that they are apt to escape the recollection of their readers and hence any instance of it occurring to a surgeon causes a feeling of surprise if not of discovery Until I met with the case recorded below I was not aware that this variety of hydrocele had been recognised and it was perhaps with a sense of disappointment that I found my "discovery had already been discovered and described The notes of the case are as follows

The patient a man aged 38 years was admitted to the Mayo Hospital, Calcutta, on July 1st 1904, for what was diagnosed by both the resident surgeon and the house surgeon as a reducible inguinal hernia and he was got ready for a radical operation on July 3rd Before he was put under chloroform I verified the presence of what appeared to be an inguinal hernia on the right side which gave an impulse on coughing, which could be readily reduced, and which descended again immediately on withdrawing the hand The usual incision was made and on reaching the sac it seemed darker than usual and was obviously distended with fluid A small opening was made in it to give exit to the fluid which was clear and of a pale straw colour, but to my astonishment this continued to flow until the amount far exceeded the capacity of the sac and I began to think that there must be ascites as well as a hernia However, the flow ceased when two and a half pints had escaped, then on looking into the sac at the internal ring it was surprising to find neither intestine nor omentum and on passing a finger through the ring nothing could be felt but the yielding sides of a smooth walled cavity the limits of which could not be reached In order to find how far this cavity extended and in what direction I passed into it the metal handle of a retractor which entered for a distance of about ten inches in directions radiating upwards and inwards from the internal ring The left index finger pushed into the sac while pressure was made on the abdomen with the other hand could feel the under surface of the liver and of the umbilicus and the intestines could be felt through the thin wall of the sac This large cavity communicated at the internal ring with the sac outside which extended thence to about an inch beyond the external ring where it ended in a blind pouch This extra abdominal sac was separated from its connexions and cut off close to the internal ring A gauze drain was passed through the internal ring into the sac within the abdomen and the skin incision was then closed There was nothing noteworthy in the after history, the gauze drain was shortened on the third day and was removed on the ninth day The abdominal sac did not fill again The patient was kept in bed for three weeks and when discharged from hospital at the end of a month the abdominal sac so far as could be ascertained was obliterated

As regards diagnosis this would depend upon the dulness on percussion of the swelling in the groin, its re-descent without gurgling after reduction, the transparence of the external swelling and the presence of an area of dulness *extending inwards or upwards from the internal ring* This form of hydrocele is one of the varieties of a hydrocele *en bissac* or a bilocular hydrocele, one pouch of which occupies the position of the cord while the other expands into the iliac and hypogastric regions of the abdomen This condition is mentioned in Treves's System of Surgery and is described by the late Sir George Humphry in his article on Diseases of the Male Organs of Generation in Holmes's "System of Surgery Humphry gives notes of two cases both on the right side and both of which suppurated after insertion of the lint of those days, he also refers to two other cases reported by Professor Syme and Lord Lister respectively There is a still more detailed description of these peritoneo vaginal hydroceles in the article by P Reclus in Duplay's "Traité de Chirurgie, [1] and it may be noted that the only case there figured is also on the right side He describes three varieties of abdominal hydrocele—viz, (1) properitoneal, the most common (2) interstitial, between the muscles of the abdominal wall, and (3) subcutaneous in front of the aponeurosis of the external oblique The explanation there offered is that the processus vaginalis having been obliterated at the internal ring and some point beyond this the non obliterated portion between these points becomes distended with fluid, constituting a hydrocele of the cord the upper end of which expands into the abdomen pushing the peritoneum before it and thus a bilocular sac is established

In order to bring about adhesion of the walls of the abdominal sac it has been recommended (1) to inject it with tincture of iodine (2) to wash it out with a rather strong solution of corrosive sublimate, (3) to drain it through the lower sac, and (4) to draw the sac out through the internal ring and to remove it But in the case of a large abdominal sac it would be unsafe to inject tincture of iodine while its removal by drawing it out would incur obvious risks if the sac had formed adhesions to the peritoneum To some extent the line of treatment would depend upon the characters of the sac such as its size thickness and adhesions to the tissues outside it Drainage after some irritation of the interior of the sac as by manual examination of it together with pressure and prolonged rest in bed sufficed to effect a cure in this case as well as in the two reported by Sir George Humphry, though it must be repeated that both of his suppurated

THE HOME OF RECOVERY —A dinner in aid of the plan for this home in Surrey was given last week at the Prince's Restaurant, Piccadilly, London W The Duke of Portland occupied the chair and explained that the home would receive 21 patients that a motor ambulance would be used for their conveyance from London and that proper surgical treatment would be provided for those whose wounds or sores were still unhealed The sum of £30 000 was needed, not for building but for permanent endowment No debts would be sanctioned and no further begging would be encouraged The sum of £5000 was needed for building and equipment and nothing would be done till the whole of the money was provided Sir Frederick Treves replying to the toast spoke of the "terrific pressure on the hospitals of London "This home, he said, "is absolutely a necessity and it is a marvel to me that it has been so long delayed *There is no scheme* that I know of that appeals more to those of us who have to do with surgery in London Lord Lytton also spoke Donations to the amount of £1335 were announced at the end of the evening

TOTAL ENUCLEATION OF THE PROSTATE IN ADVANCED OLD AGE.

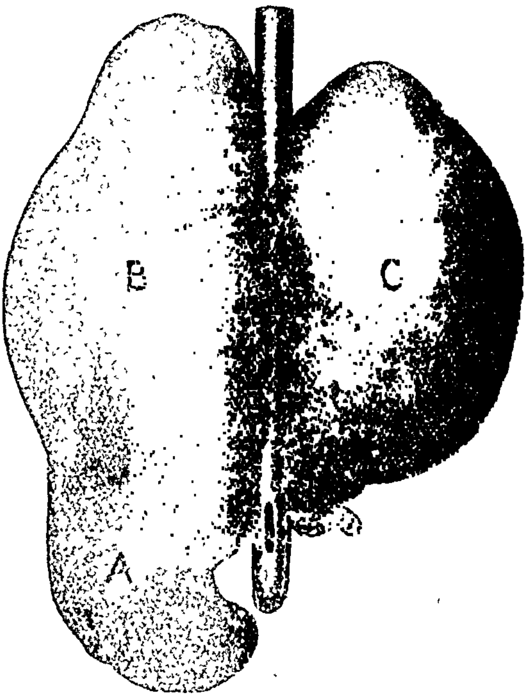
By P. J. FREYER, M.A., M.D., M.Ch. R.U.I.,
SURGEON TO KING EDWARD VII.'S HOSPITAL FOR OFFICERS AND TO ST. PETER'S HOSPITAL, LONDON.

[THE first part of this paper, which was an introductory address delivered before the Reading Pathological Society, was taken up with a description of the various steps in Mr. Freyer's operation of total enucleation of the prostate and the anatomical and pathological considerations tha render the operation feasible. These have already been published in THE LANCET. Mr. Freyer continued by directing attention to the application of the operation in the case of octogenarians.]

One of the most remarkable features of this operation is the success that has attended its employment in patients of very advanced ages. Amongst 134 patients on whom I have performed the operation to date there were seven octogenarians and one bordering on this period of life, aged 79 years. Seven of them are alive at the present time, most of them in excellent health, and all able to retain and to pass urine normally. The remaining patient, in whom the prostate was carcinomatous, after complete recovery from the operation died suddenly from heart disease. From these facts it would appear that age has little influence on the results of the operation, provided that the vital organs (and particularly the kidneys) are unaffected or fairly sound. Nevertheless, patients of this age cause much anxiety, and the operation should not be undertaken in such cases unless the most careful and tender nursing is available as well as the constant personal supervision of the surgeon. The details of these eight cases are as follows, the original numbers of the cases in the whole series being retained.

CASE 15.—The patient, aged 79 years, was seen in consultation with Mr. J. H. Scott of Camberley on June 10th, 1902. There had been prostatic symptoms for three years. The patient was completely dependent on the catheter for nine months. The catheterism was painful and accompanied by hæmorrhage at times, also orchitis. The sound was passed but no stone was found. The prostate was much enlarged per rectum, particularly on the left. It was bilobed, rather hard, but moveable over the bowel. On June 23rd, Mr. C. Carter Braine being the anæsthetist, Mr. Scott and Mr. H. Frankling assisting, I made a cystoscopic examination of the patient and saw a valvular outgrowth from the left lobe, of the size of a gooseberry, projecting into the bladder. Suprapubic cystotomy was forthwith performed. The prostate being rendered prominent in the bladder and fixed by a finger of the right hand in the rectum, with the nail of the forefinger of the left hand in the bladder I scraped through the mucous membrane over the valvular prominence and detached it from the tumour all round. With the point of the finger I then rapidly enucleated the left lobe in its capsule from the sheath and urethra and delivered it into the bladder. The right lobe was similarly enucleated and both were withdrawn from the bladder by forceps. The urethra was left uninjured, covering the catheter. There was some oozing of blood which was controlled by hot boric irrigations. A drainage tube was inserted and the abdominal wound was sutured. Mr. Braine timed the operation, which from the moment I took the scalpel to perform suprapubic cystotomy till the wound was sutured occupied ten minutes. The patient bore the operation well but was so sick from the anæsthetic that for three days he had to be fed entirely by the rectum. On June 29th the temperature rose to 103° F. and the right parotid gland suddenly swelled to a large size, and on July 2nd there was swelling of the right testicle. Both glands subsided without suppuration. What the cause of the swelling of the parotid was—whether due to chill, the result of rectal feeding, or occurring as it occasionally does after operations on the pelvic viscera and abdomen—I am unable to say. I feared at first that it might be due to septicæmia, but this was obviously not the case. Urine began to pass naturally on July 16th and the abdominal wound was completely closed on the 27th. I saw this patient recently, more than two years after the operation. He was in excellent health, had put on much flesh, and assured me that he passed and retained his urine better than at any period of his life previously to operation.

FIG. 1.

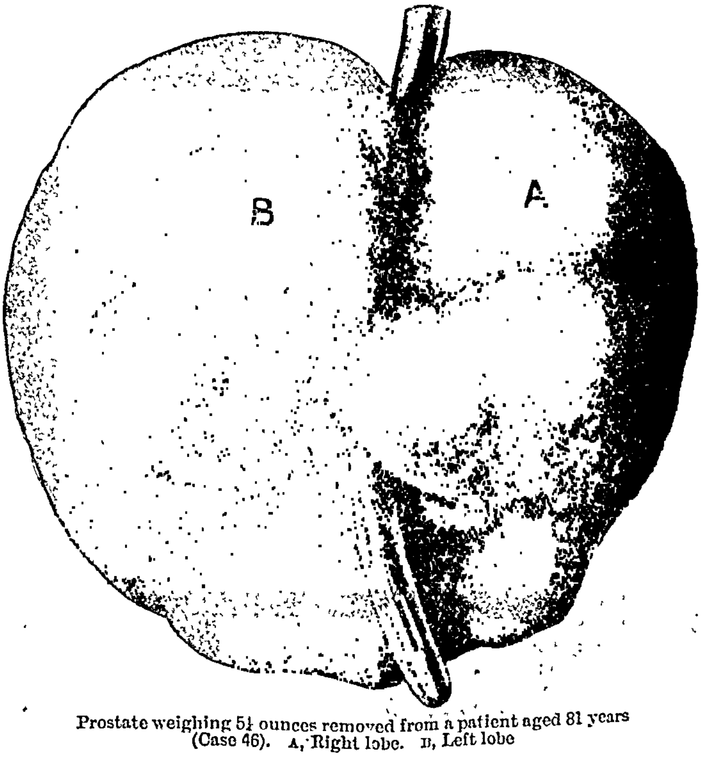


Prostate weighing 2 ounces removed from a patient aged 79 years (Case 15), actual size. C, Right lobe., B, Left lobe, continued into the bladder in the form of a so-called "middle" lobe, A. The catheter shows the position occupied by the urethra.

The prostate (Fig. 1) weighed two ounces, with each lobe enveloped in its true capsule. It is adenomatous but rather hard. It will be observed that the so-called "middle lobe" (A) is merely an outgrowth from the left lobe (B).

CASE 46.—The patient, aged 81 years, was seen in

FIG. 2.

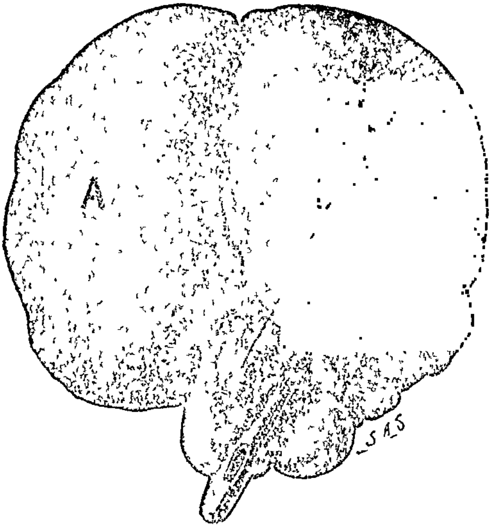


Prostate weighing 5½ ounces removed from a patient aged 81 years (Case 46). A, Right lobe. B, Left lobe consultation with Dr. H. J. Macevoy of Brondesbury on May 3rd, 1903. Prostatic symptoms had been present for ten years, gradually increasing in severity. There had been retention of urine for four years previously, relieved by catheter, which has been employed ever since. There were great frequency of micturition, intense pain at times, and hæmaturia He had been seen from time to time by various London surgeons. Double vasectomy was performed in 1900, but with no relief. His condition had been extremely miserable during the last six months. I drew off eight ounces of residual urine containing much pus and blood; there was difficulty in introducing the catheter. The prostate was enormously enlarged per rectum; it was soft, tense, and moveable. Cystoscopic examination on May 4th revealed an outgrowth of the left lobe of the prostate in the bladder of the size of a plum. The patient was in very feeble health and confined to bed. On May 13th, Mr. J. W. Thomson Walker and Dr. Macevoy assisting, and Colonel W. G. H. Henderson, I.M.S., being present, I removed the prostate entire in its capsule. Some trouble was experienced in the enucleation owing to the stoutness of the patient, the finger with difficulty reaching the aspect of the gland towards the triangular ligament. The time occupied from commencing the suprapubic wound till the prostate was delivered from the bladder was 13 minutes. There was very little bleeding and no shock. *The recovery was uneventful, the temperature remaining* normal throughout. Some urine passed naturally on June 2nd and wholly in this way on the 5th. The patient went home on the 8th, 26 days after the operation, retaining and passing his urine naturally He is now in excellent health, untroubled by any urinary *symptoms*

The prostate (Fig. 2), which weighs five and a quarter ounces, is an excellent specimen of almost [illegible] that organ.

[illegible] was seen with [illegible] 3 Prostatic symptoms had been present for 30 years and gradually increasing. The catheter had been passed in June, 1901, showing 13 ounces of residual urine. Cystitis supervened in August, with much pus in the urine and rigors. The catheter was passed five or six times daily in November, 1902. The sound was passed under an anæsthetic in July, 1903, by another surgeon but no stone was found. The patient had been entirely dependent on the catheter since then, with much pain and occasional bleeding. His general health was bad The prostate was greatly enlarged per rectum; it was broad, soft, nodular, and moveable. On Nov. 19th, Mr. Shaw and Colonel C. Little, I.M.S., being present, I removed the *prostate* entire in its capsule with several small calculi from the bladder There was considerable bleeding and the patient was feeble for some days after the operation By the 29th the suprapubic wound had closed so rapidly that it was necessary to reinsert a small tube to prevent spasm of the bladder. This was removed on Dec. 6th and on the same day the patient began to pass urine naturally The wound was closed on the 11th. On the 16th he went out for a walk I saw him two days ago. He is now, a year after operation, in excellent health and able to retain *and to pass his urine naturally.*

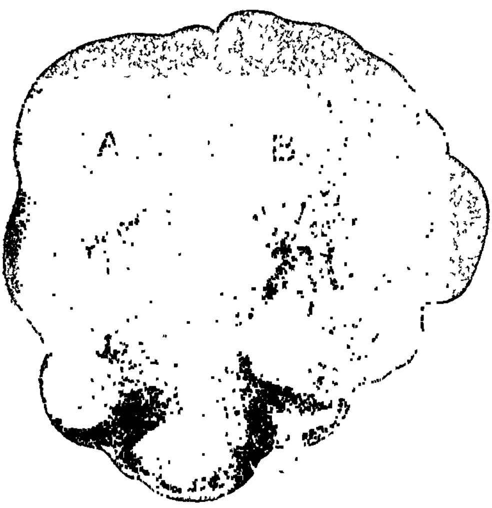
FIG. 4.



Prostate weighing 6¼ ounces removed from a patient aged 84 years (Case 70) A, Left lobe. B, Right lobe Each showing an outgrowth in the bladder

The prostate (Fig. 3) weighs four and a half ounces and is irregularly enlarged and bossy, the left lobe having been more prominent in the bladder than the right

FIG. 3.

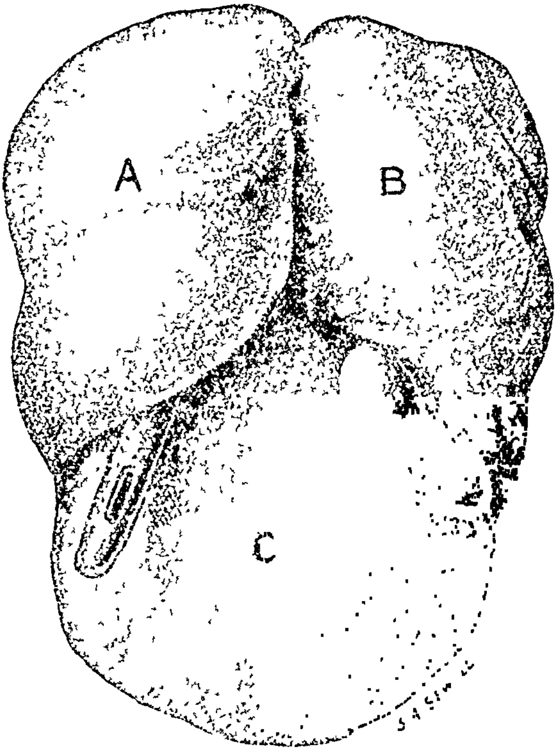


Prostate weighing 4½ ounces removed from a patient aged 81 years (Case 67). A, Left lobe B, Right lobe.

CASE 70—The patient, aged 84 years, was seen with Dr H E Bruce Porter of Windsor on Nov. 22nd, 1903 Prostatic symptoms had been present for eight years The catheter had been employed for six years and the patient had been entirely dependent thereon for five years, it was passed every two hours The urine contained much blood and ropy muco pus; it was alkaline and fœtid. The catheter passed in 13½ inches before the urine flowed; a stone could be felt grating against its end. The prostate was enormously enlarged per rectum; it was roundly bilobed, smooth, soft, and moveable The patient was emaciated, bearing the impress of terrible suffering "Life not worth living under present condition," as he put it; *morphine was given daily to* mitigate the pain. He had an intermittent and irregular pulse; the arteries stood out like whipcords all over his body. Rigors and fever occurred periodically. He came to London on Nov. 27th and his bladder was washed out twice daily. On Dec 4th, Mr. C C. Braine being the anæsthetist and Dr. Porter assisting, I opened the bladder suprapubically and found two phosphatic stones which were removed; they weighed two and a half drachms. Both ureters were dilated to such an extent that the index finger passed readily into them. The prostate was felt to be of the size and shape of a cricket-ball, and was jammed beneath the pubic arch, half of it lying in the bladder and half outside. It was enucleated entire in its capsule. Much force was required to separate it from the surrounding sheath. The time from commencing the suprapubic cystotomy till the prostate was delivered from the bladder was seven minutes. There was scarcely any bleeding or shock. The drainage-tube was removed on Dec. 7th. There was not an unfavourable symptom. No morphine had been given since the operation. "Talk of the pains of an operation," said the patient, "the last four days have been holidays from pain amongst many years." He sat up daily after Dec. 16th. He passed urine naturally by Dec. 20th. The wound was dry on the 23rd and the patient was walking about. On Jan. 2nd, 1904, he travelled home in good health and spirits, passing and retaining his urine naturally. He stated that he felt 20 years younger than his age—a truly grand old soldier who was present in the Afghan war in 1840. On July 26th last Dr. Porter wrote: "I saw old —— to-day; he looks a marvel." In spite of the putrid state of the urine before operation the wound remained healthy and was free from phosphates throughout.

The prostate (Fig. 4), which weighs six and a quarter ounces, is a fine specimen of symmetrical enlargement with a small outgrowth in the form of a lip below the orifice of the urethra. This is the oldest patient on whom I have performed this operation and I submit that the result is a great surgical triumph considering his age, the large size of the prostate, the weak state of the patient, the presence of chronic cystitis with formation of phosphatic calculi, the dilated condition of the ureters from backward pressure, indicating a probability that the kidneys were much diseased and in spite of all this the complete restoration to health and function of the bladder.

FIG. 5.



Prostate weighing 5¼ ounces, removed from a patient aged 82 years. A, Left lobe B, Right lobe, presenting a tongue shaped outgrowth, C, in the bladder.

CASE 85.—The patient, aged 82 years, was seen with Mr. J. L. Hewer of Highbury New Park on March 2nd, 1904. Prostatic symptoms had been present for 20 years and the patient had been entirely dependent on the catheter for ten years. He experienced great difficulty and pain in introducing the catheter latterly, two hours being frequently spent in manipulating the instrument before it passed. He *had had frequent attacks of cystitis, hæmorrhage, and* orchitis and had undergone seven operations for vesical calculus. He had inguinal hernia requiring a truss. The prostate was much enlarged, soft, tense, and moveable; it could be felt bimanually. The urine contained pus and mucus. On March 7th I removed the prostate entire in its capsule, Mr. Hewer assisting. The time occupied was six minutes. The operation was well borne; recovery supervened without any unfavourable symptom, the temperature remaining normal throughout. Urine passed naturally on the 23rd and the wound was dry on the 25th, 18 days after operation. The patient is now in excellent health, attending to his business daily. On July 19th he wrote to me: "The result of your operation has been entirely satisfactory. I am now able to pass and retain the urine as well as I ever did."

The prostate (Fig. 5), which weighs five and a quarter ounces, presented a large tongue-shaped outgrowth in the bladder growing from the right lobe. The rapidity with which the wound closed is remarkable in a patient aged 82 years.

CASE 96.—The patient, aged 81 years, was seen with Mr. H. Huxley on Feb. 17th, 1904. Prostatic symptoms had been present for five years. The patient was in great distress with an over-distended bladder. I passed a catheter and drew off 55 ounces of fairly clear urine. The prostate was much enlarged, rounded, smooth, and moveable. His general health was good. He passed some urine naturally for a few days but eventually he was completely dependent on the catheter. He was seen again with Mr. Huxley on May 3rd, when he travelled to London for operation, as catheter life was unbearable. His health was bad and he was very feeble. Rapid loss of flesh had taken place during the last two months. I enucleated the prostate on May 6th, Mr. Huxley and Mr. Thomson Walker assisting The gland was scarcely prominent in the bladder; it was firmly bound down by its sheath. There was hardly any bleeding. The prostate weighed two and a half ounces. Progress was most favourable till May 10th, when a severe attack of gout set in, followed by severe inflammation of the parotid glands which, however, did not suppurate. Though the wound kept clean throughout progress was slow, owing to the weak state of health. Urine was passed naturally by June 2nd and entirely per urethram by the 11th. The patient left the surgical home on the 16th and on the next day the suprapubic wound reopened. A catheter was tied in till the wound closed again. The patient can now pass and retain his urine normally and his health generally is gradually improving.

CASE 121.—The patient, aged 83 years, was seen with Dr. R. M. H. Randell of Beckenham on August 10th, 1904. The usual prostatic symptoms had been present for 12 years. He had had cystitis eight years previously, since when he had employed a catheter, latterly three times nightly, and once or twice by day. He could pass small quantities of urine naturally by day but with great frequency of micturition, attended by pain. There was difficulty in introducing the catheter, attended by bleeding. The patient was in great distress and was suffering from chronic cystitis. The prostate was greatly enlarged per rectum and was bilobed, soft, moveable, and smooth; it was easily felt bimanually. His general health was fair. On Sept. 15th, Dr. Randell assisting and Dr. F. de Havilland Hall and Mr. E. G. Renny of Colchester being present, I enucleated the prostate which weighed four ounces, in its capsule, leaving the urethra behind. The time occupied by the operation was five minutes. There were scarcely any bleeding and no shock. The patient made an uneventful recovery, urine passing naturally by Oct. 12th and the suprapubic wound being dry on the next day. He is now in good health and able to retain and to pass his urine as well as he ever did.

CASE 123.—The patient, aged 83 years, consulted me on Oct. 22nd, 1903. He had had vesical calculi crushed in 1897 and again in 1900. During the last two years he had been in great distress from pain and frequency of micturition, being out of bed every half hour by night. The prostate was not enlarged per rectum but there was a nodule in the right lobe of stony hardness. The cystoscope revealed considerable enlargement of both lobes in the bladder and under the anæsthetic the nodule in the right lobe was felt bimanually to be of considerable size and gave rise to a suspicion of malignancy. The residual urine was only two and a half ounces. Employment of a catheter was advised. I saw the patient again in June, 1904, when he was no better. He would not persist in the use of the catheter, which, he said, made him worse. *Early in September he begged for operation as* he could not sleep owing to the pain and frequency of micturition. There was rapid loss of flesh during the last few months. On [illegible] of the right lobe of the prostate (which weighed one and a quarter ounces) showed it to be carcinomatous. The patient made very favourable [illegible] and the [illegible] which he [illegible] faint, fell [illegible] 1904, I have performed the operation in a further series of 34 cases, amongst whom there were two octogenarians. To complete the record to date I will give details of these two operations.]

CASE 155.—The patient, aged 83 years, was seen with Dr. J. O. Ferrier of South Norwood on Dec. 8th, 1904. Prostatic [illegible] years; these had been much [illegible]. The patient had reten- [illegible] was entirely dependent on the catheter for ten days There were much pain and difficulty in introducing the catheter and he was in great distress from cystitis, attempting to pass urine every few minutes. The prostate was enlarged, bilobed, tense, and moveable and was felt bimanually. The patient was stout; his general health was fair; the urine contained pus and albumin. On Dec. 10th he was conveyed to London by ambulance. After washing out the bladder daily and preparing [illegible] 20th, Dr. Ferrier assisting, I [illegible] ically, removed a small urate [illegible] then enucleated the prostate, [illegible] rter ounces, entire. The time occupied was five minutes. There was very little bleeding and no shock. No unfavourable symptoms supervened. Urine commenced to pass naturally on Jan. 9th and the wound was closed on the 12th. On the 16th the patient was walking about his room and on the 25th, when he left for home, he was in good health, passing and retaining his urine as well as he ever did. On Jan. 28th Dr. Ferrier wrote: "I am exceedingly pleased to see how well a man of his age has done after your operation."

CASE 160.—The patient, aged 80 years, was sent to me by Dr. A. M. Mitchell of Guildford on Jan. 11th, 1905. Prostatic symptoms had existed for four years. Retention of urine occurred one and three-quarter years ago and was relieved by catheter which had been regularly employed since then; he had been entirely dependent thereon for one year. He had had cystitis, hæmorrhages, intense pain in the penis during and after using the catheter, and the urine, which was alkaline, contained much pus and mucus. He had been in bed for seven weeks and was so feeble that he had to be conveyed to London by ambulance. The heart was very feeble with irregular and intermittent pulse. The prostate was bilaterally enlarged, soft, smooth, and moveable. Much pain and tenderness were felt during examination which were suspected to be due to the presence of vesical calculi. The patient's condition was very distressing, the catheter being introduced with much difficulty and pain. On Jan. 16th, Mr. C. C. Braine being the anæsthetist and Dr. Mitchell assisting, I removed four phosphatic calculi, weighing 185 grains, suprapubically and then enucleated the prostate entire without difficulty. The prostate projected into the bladder in the shape of an enormously hypertrophied cervix uteri with wide, irregular os. It weighed two and a half ounces. The time occupied [illegible] which were expended in removing [illegible], well borne and there was no [illegible] satisfactory, the patient soon [illegible] ine was passed naturally on [illegible] ry on Feb. 8th. He is sitting [illegible] an pass and retain his urine (which is almost quite clear) as well as ever and will leave for the country in a few days.

Harley street, W.

Scottish Poor-Law Medical Officers' Association.—At a meeting of the executive council of this society held on Feb. 15th at Glasgow, Dr. William Cullen, vice-president, presented Mr. W. L. Muir with several handsome pieces of silver plate in appreciation of his indefatigable services as secretary of the association. The presentation was made by the unanimous wish of the association.

ENELECTROLYSIS: AN IMPROVED METHOD OF OPERATING ON SUPERFLUOUS HAIRS.

By BALMANNO SQUIRE, M.B. Lond.,
SURGEON TO THE BRITISH HOSPITAL FOR DISEASES OF THE SKIN.

THE extreme dislike evinced by most women to engaging in the habit of shaving when they are the subjects of superfluous hair, although this method is probably the best they can adopt for ridding themselves of the disfigurement, and their almost invariable insistence on having the hair removed by electrolysis, renders any improvement in operating with the electrolytic needle a desideratum. The operation as hitherto practised is by no means ideal as to the results obtainable from it even in the hands of expert operators, and instances are by no means rare in which the effects of the operation have produced considerably more disfigurement [illegible]: the procedure has consequently [illegible] liscredit. As hitherto practised, [illegible] for the direction in which the [illegible] h a view to its point reaching the root or papilla from which the hair grows and after the needle has been allowed to remain *in situ* for a period presumably long enough for the current to destroy the papilla, the hair thus operated on is seized by a pair of tweezers and very gentle traction is made on it; then if the hair comes out as if quite loose the hair papilla is considered, and with good reason, to be destroyed.

Quite recently, however, another mode of setting to work occurred to my mind—namely, to pull out the hair first and then to pass the needle into the hole left by the extraction of the hair. This difference, trivial as it seems, alters the whole character of the operation. It renders the destruction of skin that necessarily accompanies the destruction of the papilla very much less, and in consequence the scarring left after the operation is not very noticeable. It makes the operation a much more certain one—indeed, it converts it into an operation of precision. The upper lip, hitherto always by far the most difficult region to operate on, becomes as easy to deal with as the chin. One very important advantage of it is that it makes the procedure much more expeditious and another is that the pain caused by the introduction of the needle is notably less. My doubts as to this improvement before I had tried it were that in pulling out the hair first, often in itself a difficult thing to see, one at once loses one's only guide not only as to the point at which the needle should be inserted but also as to the direction in which it should be pushed; that, even if one could contrive to see the orifice of the hair follicle, one has lost in the plucked-out hair the clue to the precise direction of its slant. Then I feared that in passing the needle down the hair follicle the point would get caught in the wall of the follicle and thus diverted from the proper direction, and, lastly, I foresaw that the only test of success—namely, the hair yielding easily on traction with the tweezers—was rendered impossible. On trial, however, I found that not one of these objections was valid.

The drawbacks to the method hitherto in use are, on the contrary, by no means imaginary. The direction of the hair outside the skin is not a trustworthy indication of its direction in the substance of the skin. It shows the direction of the slant but not the degree of the slant, inasmuch as the majority of the hairs directly they issue from the skin become at once curved. I am aware that it has been claimed [illegible] that a catheterisation by th [illegible] is possible and that thus [illegible] the sharply pointed needle [illegible] considerable experience of the operation has convinced me that this is not so or at the most happens only in an extremely small percentage of the hairs operated on. As a rule the point of the needle, even when very carefully and slowly introduced, pierces the skin by the side of the follicle and arrives at its destination at a spot on one side of, and at a variable distance from, the papilla. The consequence is that an unnecessary destruction of the skin has to be produced in order that the destruction may radiate until it has reached the papilla; in short, that this has to take place visibly before the hair will come out under really gentle traction with the tweezers. Then, on pushing the needle point into the skin, however slowly, so that its electrolytic action may, so far as possible, enable it to eat its way; still the mobile and elastic skin always gets more or less pushed out of its proper place, for hairs always slant, and so the true direction of the hair gets lost. This is especially so on the extra mobile upper lip. In many instances the most practised operator finds that when he thinks he must have attained approximately the right direction the hair still sticks fast and will not come out on gentle traction, unless, indeed, a regrettable hole is at last burnt in the skin by the prolonged cauterising effect of the needle. The pushing of a needle, however fine, however pointed, and however polished, into the skin is very perceptibly resisted by the skin unless, indeed, it be done with a jerk, which is inadmissible for the purpose in question, and it pushes the skin before it even if the puncture be made perpendicularly to the surface, which is never possible in dealing with hairs on account of their pronounced slant. This is a great disadvantage of the method hitherto pursued.

As to the operation I now propose I must premise that it is quite possible to see the orifice of the hair follicle after the hair has been pulled out and that this being identified it becomes possible always to introduce the point of the needle into the hair follicle itself, a feat which is scarcely, if at all, possible to achieve unless the hair has first been pulled out. As to the direction in which the needle should be guided this can be known by carefully observing the exact direction of the hair before it is pulled out and even after this has been done considerable aid is afforded by observing the precise direction of slant and degree of slant of the neighbouring hairs. This being so it is easy to effect a true catheterisation of the hair follicle with the needle. In this manner the point of the needle touches the spot instead of arriving somewhere on one side of it. The needle if thus used enters the skin with the greatest ease, it does not in the least push the skin before it, and it does not displace the skin laterally. It has glided down a pre-existing tube which a No. 12 sewing needle fits quite easily. The introduction of the needle is much more expeditious, also it has to be left in the skin for a much shorter time because only a very short electrolytic action is required to destroy the papilla when the point of the needle is in actual contact with it. The whole process thus becomes much more expeditious. A much greater number of hairs can be operated on in a given time. The destruction of skin each time the needle is inserted is infinitely less and the scarring left is reduced to a minimum, not only by reason of the shorter action required of the current when the papilla has been reached but also by reason of the far more rapid introduction of the needle. It may, perhaps, be objected that one hereby loses one's test of success—the easy withdrawal with the tweezers of a loosened hair. One gains, however, in exchange a new and equally satisfying test. Here I must explain that I soon learnt that it is better to use the butt end (the eye end) of the needle than its pointed end. It slips down just as easily—indeed, more easily—because the point end is apt to stick and get caught in the walls of the follicle and is thus diverted from its aim. Now when one finds that the butt end of a needle enters the skin far more easily than the point, as used in the ordinary way in the hitherto practised methods, one may be reasonably sure that it is passing down the follicle.

A word now as to the means of identifying the orifice of a hair follicle after the hair has been pulled out. The orifice is, of course, not boldly obvious; a little practice is naturally a great aid in discerning it. One is assisted too by taking the bearings of the orifice before the hair is pulled out; it may, for example, be in a line with the point of emergence of two other hairs and the three may be equidistant or what not. In any case, after pulling out the hair with the tweezers it is necessary to keep one's gaze fixed on the orifice until the needle has been inserted into it. The butt-end of the needle ought to be allowed to remain in the orifice for an instant so as to burn a minute funnel in it before the needle is allowed to glide in. For this instant the needle should be held perpendicularly to the surface and then slanted to approximately the right direction and the right slant. I say only approximately, for it is one of the great advantages of this method that, that being so, as soon as the needle is once engaged in the follicle it becomes guided in its further progress by the follicle itself. I have to admit that in performing this operation I have the great advantage of being myopic to – 8 dioptres but anyone who will put on spectacles of, say, + 8 dioptres, will be in exactly the same position as myself for identifying the orifice of the hair follicle. The orifice under favourable conditions looks like a very minute needle-prick. I would suggest as a distinctive name for this method of operating the word "enelectrolysis."

Weymouth-street, W.

LACERATION OF THE ABDOMINAL WALL THE RESULT OF BEAR-BITE SIMULATING AN ABDOMINAL TUMOUR.

BY V. S. UMACHIGI, L.M. & S.

A MAN, aged 45 years, with a red fungoid pendulous tumour in the left hypochondriac region, was brought to the surgery from Castle-Rock on May 14th. The patient while returning home from his work in the jungles one evening was attacked by a wild bear. He received several nail-wounds on his chest and abdomen and a severe bite on the left side of his abdomen. He struggled hard with the bear, which at last ran away, leaving him disabled. After the injury a fleshy pendulous mass was seen protruding from the skin wound on his abdomen. The patient was weltering in blood on the spot and was helped to his hut by his companions. An attempt was there made by his fellow coolies to treat the wounds with some dark stuff. As he did not feel any relief from these applications and as the tumour began to increase in size they thought it fit to seek for better treatment and therefore took him to Castle-Rock exactly one week after he had received the injury. He was thence brought to Belgaum and into our surgery by a kind gentleman. On admission the patient looked quite exhausted and his condition appeared to be critical; his pulse was weak, his extremities were cold, and his face was pinched and drawn. His voice was low and he felt thirsty. There was no history of nausea or vomiting. He preferred the recumbent posture to sitting up, as the tension was relieved thereby. He said that he had felt a dragging pain throughout the week in the gastric region. On palpation the stomach was found to be distended and the spleen (which was malarial) was considerably enlarged; the liver was normal. The tumour presented beneath the costal arch of the left hypochondriac region. It had a fungoid appearance more or less pear-shaped with a notch at the fundus, the most dependent part, and had a pedunculated neck as it issued forth from the skin wound. It measured six inches long, seven inches around the fundus, and five inches around its peduncle. The thickness of the tumour was about two inches. The whole surface was looking very fleshy and was covered with stinking and thick pus. When the tumour was raised and the posterior surface exposed a central notch that extended nearly as far as half the depth of the tumour was noticed (which appeared to be the mark left by the teeth of the animal).

The tumour felt like an elastic mass. On gentle percussion a dull note could be elicited and the patient felt no pain. A probe could be run around the peduncle of the tumour, between it and the border of the skin wound. The probe was, however, not forced deeper down for fear of entering the peritoneal cavity if it should be an abdominal tumour. The situation of the tumour just near the enlarged spleen, a marked notch on the border and another on the posterior surface which very much resembled the hilum, and the elastic feel of the tumour led one to believe for some time that it might be an accessory spleen. The possibility of a portion of the transverse colon protruding was also not lost sight of. Hence, to make sure of its nature a small piece of it at the inner angle of the fundus was removed. This piece showed mostly fibrous structure with a rich supply of blood. Above all this, the patient having lived eight days after the receipt of the injury made me very doubtful of the tumour being abdominal unless localised peritonitis should have prevented it from infecting the general peritoneal cavity. Having made the usual preparations for the operation the tumour was removed; profuse hæmorrhage from several cut vessels was controlled by hæmostatic forceps and ligaturing. Trying to dissect it out at the peduncle, its firm attachment at the costal arch without any connexion with the abdominal cavity was noticed. The wound being dressed the patient was kept in bed and was directed to take perfect rest lest bleeding might set in again.

On examining the tumour after removal it had a film of thick pus all over the surface, which on being cleaned showed a nodular surface over which were seen a few hair follicles scattered about. It was therefore certain that the surface was skin structure and on making a section of the tumour it showed abundant fibrous tissue with traces of adipose tissue and muscle fibres. This was confirmed by microscopic examination. The patient was repeatedly questioned as to whether he had noticed any tumour or swelling at the seat before the receipt of the injury but he and his friends emphatically denied the presence of any.

The occurrence of a tumour of mixed type consisting of fibrous, adipose, and muscular tissues with a capsule of cutaneous structure as a result of bear-bite leads one to believe that laceration of a few fibres of the first digitation of the external oblique muscle together with the overlying skin and subcutaneous tissue took place by the severe bite, and as the lacerated piece had a good supply of nutrient vessels it did not slough off but on the contrary the proliferating overlying skin encapsuled the whole mass. The discharge of the wound kept it soaking and thus disguised its real nature by rendering it sodden and fungoid. The patient progressed very satisfactorily after the removal of the tumour but he had two attacks of malarial fever during his stay under treatment. These were checked by a few doses of quinine. In 13 days the wound healed and he was discharged relieved on May 26th.

EAST LONDON HOSPITAL FOR CHILDREN, SHADWELL.

A CASE OF EXTRAPERITONEAL URETERO-LITHOTOMY IN A CHILD, AGED THREE YEARS.[1]

(Under the care of Mr. HENRY BETHAM ROBINSON.)

ON June 17th, 1904, a male child, aged three years, was admitted to the East London Hospital for Children, Shadwell. On the 16th he had pain in the penis, which was worse on running about, and in the evening he passed small quantities of urine frequently with great penile pain but no blood which the mother looked out for. She gave him castor oil and the [illegible] He was admitted [illegible] ving passed urine [illegible] acted calculus in the bulb with the bladder distended up to the umbilicus. Very shortly afterwards this stone was cut down on and removed with a scoop and there was a free flow of clear urine. The wound in the urethra was closed with fine silk and the skin wound was only partially closed, the remainder being lightly packed with gauze. Before closing the urethral wound a sound was passed into the bladder but no other stone was detected. A bimanual examination confirmed this and gave some more information, for a small hard lump was felt on the left side of the pelvis just below its brim, [illegible] ureter; [illegible] ng how [illegible] perhaps [illegible] determined to watch it for a few days. The urethral wound healed without any leakage and as on examination at the end of a week the ureteral calculus remained in the same position Mr. Robinson assumed that it was fixed and arranged to remove it. The urethral calculus was of about the size and shape of a cherry-stone, measuring seven-sixteenths of an inch by three-sixteenths of an inch and showing no facets.

The operation of uretero-lithotomy was performed on the 28th. A curved incision was made on the left side as if to tie the external iliac artery and the peritoneum was pushed upwards and inwards till the inner side of the vessels was reached. The little hard lump in the ureter was felt just below the brim of the pelvis and the delicate fat was separated to expose the ureter. A finger in the rectum enabled the ureter to be pushed well up into the wound; a small longitudinal incision was made down on to the stone which was lifted out with a small scoop. There was an immediate gush of pale odourless urine estimated at about two ounces, so that although no enlargement of the kidney could be made out there must have been considerable distension of its pelvis and calyces. A fine catgut stitch was put through the outer coats of the ureter, avoiding the mucous membrane, and a small drainage tube with a gauze wick inside was placed in close relation with the ureteral wound. The muscles and the skin were sewn up together with horsehair. The calculus was of oval shape, slightly flattened, and roughened on its outer side with a coating of oxalates. It measured just under three-sixteenths of an inch in length and two-sixteenths at its thickest diameter. Section showed it to be composed of alternating laminæ of oxalates and uric acid, the nucleus apparently being oxalates. On the 29th the wound was dressed and the gauze wick was removed and renewed. There had been some discharge of urine into the dressings. The child's condition was most satisfactory. The drainage-tube was taken out on the third day, the gauze being only a little damp, but a piece of gauze was replaced between the lips of the wound. After the fourth day there was no suspicion of any leakage of urine. The child's state was perfect, a normal quantity of urine being passed and at regular intervals. There had been no blood in the urine since the operation. There was never any rise of temperature after the operation. The wound was quite healed on July 13th.

Remarks by Mr. ROBINSON.—On two previous occasions I have elsewhere recorded successful cases of extraperitoneal uretero-lithotomy occurring in adults. Reference to other published cases shows no instance where this operation has been previously performed at such an early age and this fact alone, *apart from the desirability of recording all these* cases, makes this one worthy of notice. The experience of my three cases enables me to state that it is a far easier operation in the child than in the adult for the following reasons—viz., the thickness of the soft parts is less, the peritoneum strips back more readily owing to the small amount and the delicate nature of the subperitoneal connective tissue (although great care must be taken not to wound the very thin peritoneum), and the small size of the pelvis with the abdominal position of the bladder enables the finger in the rectum to push the ureter with the impacted stone well up into the wound instead of having to work at the bottom of a deep space.

One point brought out in this case I would wish to emphasise—viz., that with an impacted urethral calculus it should not be assumed that this is the only one. Examination of the bladder with sound and bimanually as well as palpation of the abdomen may discover a second or more stones which, if left behind, may produce serious results; in this case especially the unsuspected impacted ureteral stone would assuredly have caused hydronephrosis if left *in situ*. On the technique of the operation there is nothing to comment. It was extraperitoneal, as is now firmly established it should be. The lips of the ureteral wound were brought together with catgut which did not go through the whole thickness of its wall; if possible to do this it is better as it limits, if not prevents, the discharge of urine and induces rapid healing. Of course, drainage down to the ureter must be still used to circumvent any urinary extravasation.

MEATH HOSPITAL, DUBLIN.

A CASE OF RICHTER'S HERNIA.

(Under the care of Dr. R. LANE JOYNT.)

A WOMAN, aged 75 years, was admitted to the Meath Hospital, Dublin, on Dec. 27th, 1904, suffering from a strangulated hernia. She had been seen early that day by the dispensary medical officer of the district in which she lived, who diagnosed this condition and advised her instant removal to hospital for operation. She had been constipated for five days, had noticed pain in the left groin for two days, and had vomiting occasionally during the day preceding her admission. The pain was not excessive; the swelling though hard was freely moveable, in fact so much so as to give the idea of a pedicle beneath the tumour in the left femoral region. The patient was a thin spare woman and seemed not much concerned at her condition. She could give no exact statement as to the duration of the constipation or about the onset or extent of her vomiting. She stated that the tumour "might have been there" three months before but evidently until the medical man found it and it caused her pain she had thought nothing about it. She had no rise of temperature on admission but slight pain on examination and a pulse of 105. Her arteries were very rigid and tortuous. Dr. Joynt saw her on her arrival in hospital and decided to operate at once.

---

[1] A case read before the Clinical Society of London on Feb. 10th, 1905.

The operation was briefly as follows. The hernia was cut down upon. A globular piece of gut one and a quarter inches in diameter was in the sac, the neck of which was deep, and any attempt at division of the stricture from within was impossible without risk to the gut and, moreover, would not allow of inspection of the strangulated portion. Accordingly, prolonging the skin incision vertically upwards, Dr. Joynt opened the abdominal cavity by separating the muscles half an inch above Poupart's ligament. From within a coil of ileum was found tightly caught in the left femoral ring and to free it Poupart's ligament was divided vertically. The hernia embraced two-thirds of the lumen of the bowel, the part protruded being expanded like a ball on the bowel. This was at once excised and a Murphy's button was inserted. The sac was ligatured, the cut Poupart's ligament was sewed to itself and also to the pectineal fascia, and the abdomen and the femoral portion of the wound were closed without drainage. The patient made a good recovery and the button was passed on the fourteenth day.

Remarks by Dr. JOYNT.—A valuable and instructive lecture on Richter's Hernia having appeared in THE LANCET of Jan 28th, p. 205, by Mr. V. Warren Low, the above case may prove of interest, bearing out the many points laid stress on by Mr. Low and raising some others worthy of consideration. Now, the interesting points in such a case are the following: (1) the diagnosis; (2) the variation of the symptoms from the text-book type of "strangulation"; (3) the influence of age in modifying these symptoms; (4) the absolute necessity for operation in all cases of hernia giving any trouble; and (5) the question of how to free the sac rapidly in a way that complies with the proper inspection and treatment of the gut and leaves least damage to the abdominal wall.

Now as to diagnosis. Mr. Low has dealt very fully with that. To the operating surgeon it resolves itself into judging whether the patient is fit or not to undergo the operation. Every case not obviously *in extremis* ought to be operated on. The practitioner who may first see the case should remember that a recent hernia, a femoral hernia, and a small hernia are all especially dangerous; that old age seems to eliminate the violent pain and fever so often seen in robust adults; that gangrene of a hernia occurs with rapidity in old people, at times apparently after from 12 to 24 hours only have elapsed since acute symptoms set in; that chronic constipation from atony occurring in old patients may lead them to disregard constipation as a serious matter and they may make misleading statements about the regularity of their motions; and, finally, the great probability of small recent hernias being "partial" ones. These are known to be very dangerous and to give rise to anomalous symptoms. Old age unquestionably abates the number and severity of the symptoms, while it accelerates the fatality. Of the necessity for prompt operation little need be said. Taxis in a hernia which is recognised as the seat of present trouble ought to be banished to the limbo of the past like the swallowing of metallic mercury and lead bullets.

The opinion of a competent physician who may have seen such a case prior to its coming under the care of the operating surgeon ought not to be disregarded, although active symptoms are wanting when the case is seen by the latter. To wait for the reappearance of symptoms in the presence of a tumour would be to lose valuable time. The hernia has given trouble. It must be dangerous, especially in old people; how much so we do not know. Operation *per se* is not dangerous and nothing but an unrestricted operation will allow the condition present to be made out clearly and dealt with. To free the hernia is not so easy as may at first sight appear. The acute angle which the strangulated gut makes round the sharp margins of the ring prevents the safe introduction of the hernia bistoury. Even supposing that with due care and skill it is introduced why should such an uncertain, blind, and unsurgical method be tried? In the great majority of cases it would no doubt give sufficient freedom for the gut to be reduced but not to pull it down to inspect it sufficiently without having to exercise undue traction on the injured portion. I refer, of course, here only to femoral hernia and much less does the old method give facility to do any end-to-end anastomosis and would, moreover, negative the use of the button. Now it is well known that the most injured portion of a hernia is where the healthy bowel meets the protruded part and this part must be examined. If the surgeon has freed the bowel to his satisfaction I hold that if a partial hernia is found one ought to go further and to consider the following. The extrusion of a portion of the lumen of the bowel through an aperture argues the application of great pressure from within, much greater than is necessary for the production of a common hernia. The edges of the ring are sharper and more unyielding in femoral than in inguinal hernia and in consequence the portion of gut extruded has been subjected to a degree of injury which makes its recovery highly doubtful, however "glossy" or viable it may seem at the time it is inspected. Most men have experience of cases where though everything seemed right at the time of operation yet subsequently at post-mortem examinations necrosis or ulcerations were found of the originally strangulated gut. By an operation conducted from above—i.e., through the abdomen as well as from below—safety can be insured to the gut, if as yet unopened by gangrene, and so avoidance of risk to the peritoneum. Risk to the deep epigastric artery or an aberrant obturator artery is avoided, while ligation, if necessary, is rendered easy and a fair field is secured for whatever method of completing the operation may be deemed advisable.

Now, as to freeing the so-called constriction, in my case Gimbernat's ligament was not the cause but the deep crural arch and Poupart's ligament had been pressed into one sharp-edged band and Hey's ligament had been pressed upwards until it coincided with Poupart's ligament. This mass I divided at once in this case without hesitation, because the patient was old (75 years) and feeble and I had already taken some time in carefully cutting down on the hernia proper, and she being old a weakness of her abdominal walls would not be so serious as in a young active person. Further, as time was all important I used a button in preference to suture for the resection. I resected the bowel because of the mechanical reasons mentioned above, also that for one reason or another cases of Richter's hernia have a high mortality and my own experience up to the present has borne this out. Other methods, of course, occur to one as suitable in certain cases. In younger subjects every effort should be made to preserve Poupart's ligament, possibly dealing with the hernia proper by converting it into a fæcal fistula and so relieving the obstruction, and subsequently or at the time doing a lateral anastomosis between the pieces of bowel continuous to the hernial portion. This presupposes that adhesions have formed between the hernia and the ring. Here we are met with uncertainty. This would suggest itself as feasible where gangrene with rupture of the hernia had occurred into the sac with perhaps a localised abscess, but unhappily this argues a neglected case, and it is more than likely the opened bowel has receded into the abdominal cavity and caused general peritonitis. Again, seldom are such adhesions found in strangulated recent hernia and to rely on them if present would be dangerous. I have never met with this class of adhesion myself but if I did I should not rely on their holding power. The moveable bowel is held to an immoveable ring; the pressure of intestinal contents, the abdominal pressure, and peristaltic action can only act in one way—viz., to tear them apart. If the gut were gangrenous then the safer procedure would be to clamp both portions of the gut within the abdomen, to withdraw and to remove the injured portion, to excise the sac and to wall off the general abdominal cavity with sponges to protect it as much as possible from infection. If the condition of the patient permitted it I should join up the gut, if not, I should use Paul's tubes and subsequently resect the bowel when the patient had recovered from the first operation.

In conclusion, femoral hernia should be looked on as a very grave condition, most probably of the partial hernia kind and as such calling for early and sweeping measures; taxis of any sort is dangerous (the herniotome should be laid aside) and the force required to produce it is great, therefore the damage is great Had I met with bowel in an ordinary case of hernia presenting the naked eye appearance seen in this case I should certainly have hesitated to excise it I think the success of this case may be attributed to the early period at which the operation was performed and the excision of the bowel left no potential cause of mischief behind In spite of the severance of Poupart s ligament there has so far been no evidence of a hernia there

PATHOLOGICAL SOCIETY OF LONDON

Blood Glands as Pathogenic Factors in the Production of Diabetes and Obesity —Leucocythæmia with Change of Type from Spleno medullary to Lymphatic

A MEETING of this society was held on Feb 21st, Mr R J GODLEE being in the chair

Dr ARNOLD LORAND made a communication on Blood Glands as Pathogenic Factors in the Production of Diabetes and Obesity Dr Lorand laid stress on the important influence exerted by the internal secretion of the blood glands on all the vital processes of the body and pointed out that the influence of the thyroid, the sexual glands and the hypophysis was in the direction of increasing oxidation Insufficiency of these organs led to a diminution of oxidation All blood glands stood in close relation to one another, pathological changes in one being followed by alterations in others Extirpation of the pancreas in four dogs was followed by enlargement of vesicles and considerable increase in the colloid substance of the thyroid The effects of increased colloid secretion were seen in cases of exophthalmic goitre in which the symptoms resembled those produced by the administration of large quantities of thyroid tablets This condition of thyroidism, especially when it was associated with pathological changes in the pancreas

which presented similarities in their structure to that of the parathyroids the medullary part of the adrenals and the interstitial cells of the testicles The secretion of these islets was probably under the influence of a nervous mechanism and it was necessary to take this into account in explaining those cases of diabet
changes were found in the gland
of the pancreas had been desc
disease and acromegaly associated with diabetes Glycosuria was comparatively frequent in exophthalmic goitre but was unknown in connexion with myxœdema and in the latter condition could not even be produced by the ingestion of large quantities of grape sugar Extirpation of the thyroid was followed by increase in the number and perhaps new formation of

Dr C H MELLAND reported a case of Leucocythæmia with change of type from the spleno medullary to the lymphatic A woman aged 35 years, came under observation in June 1904 The symptoms of general weakness dated from Christmas 1903 and about two months later a swelling had been noticed in the abdomen On examination the spleen was found to occupy the whole of the left side of the abdomen but there was no evidence of enlargement of lymphatic glands The most noticeable feature in the examination of the blood was the large increase in the number of large lymphocytes which at first were as numerous as 46 per cent and later as 83 per cent, of all the white cells In six other cases he had found the average to be about 14 per cent The myelocytes formed at first 22 per cent and later 4 per cent of the leucocytes In spite of treatment the patient died on Sept 17th Post mortem the spleen weighed 26 ounces the liver showed small aggregations of white cells and the lymphatic glands no enlargement or evidence of hyperactivity The bone marrow contained very few eosinophilic or neutrophilic myelocytes and consisted almost entirely of non granular cells similar to the large lymphocytes of the blood Dr Melland had come to the conclusion that the large lymphocytes really represented myelocytes which had undergone retrograde changes and he had been able to trace all gradations from large cells with no true granules but with a certain amount of basophilic stippling up to the typical neutrophilic myelocyte He was inclined to regard his case therefore, as a pure but acute spleno medullary leucocythæmia and not one in which the spleno medullary and lymphatic types were mixed —Mr L S DUDGEON referred to the important part played by the hæmolymph glands as well as the bone marrow in these cases and said that he had sometimes found the thymus much enlarged He preferred the terms myelæmia and lymphocythæmia to those used by Dr Melland and emphasised the difference in the blood conditions found in the two varieties —Dr F PARKES WEBER referred to another case of acute leukæmia which he was about to publish and which tended to confirm Dr Melland s views with regard to the derivation of the large non granular cells in the blood In the terminal stages the white cell count fell to 3000 per cubic millimetre and all these presented the characters of large lymphocytes —Dr R HUTCHISON asked whether Dr Melland had formed an opinion as to the possible origina

forms of leucocythæmia were very ill defined —Dr H BATTY SHAW agreed with Dr Melland and the latter replied

symptoms
simulated those of intracranial tumour The patient received a blow on the head in 1898 which caused temporary loss of consciousness Gradually symptoms of cerebral tumour developed and these symptoms continued until

June, 1903, when clear fluid commenced to flow from the right nostril and very soon improvement set in, followed by complete recovery in the course of a few weeks.—Mr. F. C. LARKIN, Dr. R. CATON, Dr. W. B. WARRINGTON, Dr. F. A. GILL, Dr. R. J. M. BUCHANAN, Dr. J. HILL ABRAM, and Mr. W. THELWALL THOMAS discussed the case.

Dr. A. G. GULLAN read notes of two cases of Addison's Disease in which he had administered Suprarenal Extract. In the first case, that of a young man, in whom the symptoms of the disease were well marked, 15 grains of the extract were given thrice daily but with only temporary relief, the patient dying seven weeks later. At the post-mortem examination no signs of tubercle were found except in the suprarenal bodies which were both enlarged and destroyed by caseous masses evidently of a tuberculous nature. In the second case, that of a woman, the symptoms were less severe and she had benefited greatly by taking 20 grains of the extract thrice daily.

Mr. DAMER HARRISSON opened a discussion on the Union of Nerves after Division He gave a short history of the subject, physiological and surgical. The more recent histological observations which support the theory of coalescence and the process of regeneration in the peripheral end of a divided nerve were described, together with the criticisms of Mott, Halliburton, and Edmunds. On the physiological side he advanced the view that the weight of evidence was on the side of the outgrowth theory and brought forward a series of observations made by himself and Professor F. Gotch after division and suture of the sciatic nerve in the rabbit which proved that sensation reflexes appeared first in the peripheral end nearest the point of suture and at later periods at the more distant points in the peripheral end. With regard to the motor response this appeared at an earlier date in proportion to the nearness of the division and suture to the muscles. These facts were difficult to explain by means of the coalescence theory and strongly supported the outgrowth theory.—Dr. ROBERT KENNEDY said that from the clinical point of view there was a well-established observation which the central theory of regeneration of nerves could not explain—namely, the early return of sensation after secondary suture of a divided nerve. Ranvier's view did not explain this rapid restoration, for, in the first place, unnaturally rapid growth of new nerve fibres from the central end would be required, as no sensation could be felt until the axis cylinders had reached the end organs. In the second place, there would be a difference of time in the reappearance of sensation accordingly as the section of the nerve was near or far removed from the end organs, which there was not. As regards suture of the nerve immediately after section, sensation took much longer to appear, and this was what would be expected, as time was required for regeneration of the new fibres in the distal segment. When suture was performed at a time remote from section the distal segment had had time to form its new nerve fibres. The only difficulty was to explain the very early passage of impulses across the plane of suture, but this was probably brought about by the junction of neurilemma cells newly formed from the central and peripheral ends, the gap being thus bridged, the impulses apparently having the power to pass along the protoplasm of such cells. The reason why motion recovered later than sensation was owing to the rapid degeneration of the muscles after nerve section, which degeneration must first be recovered from. From observations made in the past few years Dr. Kennedy was of opinion that muscular tissue never completely degenerated, although separated from the nerve centres for long periods. A series of microphotographs were shown illustrating his views of nerve regeneration in the distal segment as opposed to the recent explanation advanced by Langley and Anderson.—Professor C. S. SHERRINGTON said that he favoured the peripheral rather than the central theory of nerve regeneration and remarked that after removal of a spinal ganglion delicate nerve fibres could be found in the portion of the root attached to the cord.—Dr. W. B. WARRINGTON called attention to certain alterations in the nerve cell which took place after section of its axone. In this condition, known as chromatolysis, the cells assumed the embryological form in preparation for renewed activity. Chromatolysis occurred in nearly all the cells of the spinal ganglia when the section was made on the peripheral side but not at all when the posterior root was divided. In the former case the nerve fibres regenerated but not in the latter. Similarly, after section of the anterior root nearly all the cells of the corresponding segment in the vertebral horn underwent chromatolysis and ultimately repaired, but after cutting off the incoming impulses by division of the posterior roots and thus producing a permanent isolation, some of the cells of the anterior horn atrophied and underwent complete degeneration. It was submitted that these experiments furnished evidence of the important part taken by the cell in the regeneration of a nerve fibre.—Mr. J. S. MACDONALD and the PRESIDENT also took part in the discussion.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Recurring Torsion of the Spermatic Cord.—Massage in Cardiac Dilatation.—Bradycardia.

A MEETING of this society was held on Feb. 1st, Professor JOHN CHIENE, the President, being in the chair.

Mr. J. W. DOWDEN read a paper on Recurring Torsion of the Spermatic Cord. It was based on five cases which had come under Mr. Dowden's own observation and on five other recorded cases. The varieties of this affection had been classified by Perry as (1) acute, where there was one sudden and severe attack; and (2) "recurring," where the attacks were more or less frequent with or without the eventual onset of an acute attack. The main predisposing factor was the manner in which the testicle, epididymis, and part of the cord were covered entirely by visceral tunica vaginalis and so hung free in the serous sac, giving rise to a condition of "floating testicle." There was also a broad arrangement of the cord with its constituents grouped in two parts, the vas deferens at one free border and passing to the globus minor, while the main vascular structures at the other free border passed to the globus major ("intermesorchial separation of the cord"). Puberty was a predisposing factor, as it was also in acute torsion. In six out of the ten cases the testicle was a descended one. Both sides were equally affected. The patients gave a history of attacks from time to time of sudden pain in the testicle associated with collapse, vomiting, and great local tenderness with (in a few hours) swelling of the testicle. Sudden relief of the severe symptoms occurred with the disappearance of the swelling in about 24 hours. Such attacks might go on for years. The condition could be distinguished from epididymo-orchitis by the suddenness of the onset and the severity of the collapse. After swelling had occurred in the scrotum a strangulated hernia might be simulated but pain followed in some hours by swelling was the main distinctive sign of torsion. A case of an infant, aged five months, and another of a child, aged three years, showed that recurring torsion might happen in infancy. The direction of the twist was ascertained in eight cases and in seven it was from without inwards and the twist varied from half a turn to two turns. The treatment in an attack was to perform detorsion and if this failed an immediate operation to untwist and to fix the testicle was required. In the interval fixation of the testicle should be carried out by clipping away the parietal tunica vaginalis and suturing the testicle to the scrotum.—Mr. DAVID WALLACE and Mr. ALEXANDER MILES took part in the discussion.

Dr. R. A. FLEMING read a paper on Massage, Passive Movements, and Modified Resisted Exercises in the Treatment of Advanced Cardiac Dilatation, in which rest and cardiac tonics had failed to yield further benefit. He thought that the exercises gave tone to the heart where it was possible for the myocardium to respond at all and they probably did so by dilating the vessels and relieving the over-burdened heart. Careful percussion of the cardiac right and left borders, taken along with the position of the apex beat, yielded accurate data as to the contraction of a dilated heart. The method of treatment consisted in successive periods of daily massage, followed from seven to ten days later by passive movements of the arms and legs and after other seven to ten days by resisted exercises. The patient was not allowed out of bed during the period of from 21 to 30 days and the exercises were limited, therefore, to those which could be performed in bed. Clinical details were given of ten cases, two of which were cases of aortic and mitral incompetence and in neither of these two was the treatment successful. In the remaining eight cases success followed the treatment, the patients were allowed up after the period of resisted exercises was finished and were made to walk slowly for a few minutes, and the period of active exercise thus taken was gradually lengthened day by day One of the eight patients speedily relapsed but with six the results were extremely satisfactory Periods varying from two years to six months have elapsed since treatment was stopped and all the six retain the degree of improvement gained —Dr G A GIBSON said that resisted movements were i[illegible] of massage could not [illegible] did [illegible] nse [illegible] 'apex beat [illegible] was that it was caused by the left ventricle The "apex beat was not caused by the true apex of the heart in the cases referred to so that the only safe guide as to the size of the heart was percussion

Dr GIBSON contributed a paper on Bradycardia He said that this condition had been described by many writers as by Morgagni who recorded two examples in 1762 by Stokes by Charcot and by Huchard Then Broadbent had described paroxysmal bradycardia associated with apoplectic or epileptiform attacks The condition had also been treated of by McKenzie, His Osler and others After an enumeration of many exoteric causes Dr Gibson said that of the esoteric causes the intrinsic factors concerned with the heart often led to bradycardia There were cases in which the whole heart participated in the lessened rate where probably the venous sinuses have lost some of their irritability In other cases the auricular portion of the heart beat two or three times for each ventricular systole Several instances of this have been proved by simultaneous tracings from the jugular veins and the apex beat or radial pulse *In certain of these neither the apex beat nor the radial pulse* showed the least sign o[illegible] to the auricular systole but [illegible] little impulses corresponding [illegible] were two chief varieties of the affection in one of which the alteration in rate was constant while in the other it was paroxysmal, though the one variety might pass into the other The clinical features might be inconspicuous or might be very disturbing In the mild form of persistent bradycardia there were weakness and breathlessness with occasionally angina *In the paroxysmal form faintness and* giddiness associated with apoplectic or epileptic attacks were present In many cases digestive disturbances were found and more rarely glycosuria or some other symptom pointing to bulbar disease In the persistent form of the affection it was probable that the great factors which induced the condition were myocardial and arterial lesions while in the paroxysmal form changes in the cerebral vessels were probably the causal factors In sclerosis of the cerebral vessels the blood supply to the brain was inadequate to *meet any stress and ineffective when the stress went* beyond a certain point Thus a condition of irritable weakness of the inhibitory mechanism was produced and impulses were sent down to the heart which led to an attack As regards treatment rest was the most important therapeutic agent Respiratory exercises were also of real importance and of course attention to digestion was required Amongst drugs iodides and hydriodic acid were most beneficial in attempting to restore a healthy condition of heart and vessels, nitrites or nitroglycerine were useful if there was any tendency to vascular spasm, bromides were good in lessening the action of the vagus while strychnine and digitalis or strophanthus were of value where cardiac failure threatened —Dr JAMES MACKENZIE (Burnley) and Dr RUSSELL took part in the ensuing discussion

ROYAL ACADEMY OF MEDICINE IN IRELAND

SECTION OF OBSTETRICS

Physometric Uterus —Cystic Endometritis —Bossi s Dilator

A MEETING of this section was held on Feb 3rd Dr ALFRED J SMITH the President being in the chair

The PRESIDENT showed a rare specimen—a large Physometric Uterus The patient was delivered early in October 1904 of twins (at the sixth month) both dead and beginning to decompose On the fourth day after delivery she had a severe rigor, with a temperature of 106°F Her medical [illegible] itll [illegible] ame [illegible] she was *in evident distress from distension* with a temperature of 102 6 and a pulse rate of 120 Examination under ether was unsatisfactory as nothing could be mapped out The diagnosis was not made until the abdomen was opened Numerous discoloured gangrenous looking patches were found and hysterectomy was performed, fortunately without rupture Examination of the contents was postponed as the President wished to show the large uterus in its distended condition The patient made an uninterrupted recovery —Dr FREDERIC W KIDD asked how the gas had been kept *in the specimen? The only similar case he had seen was* an accumulation of gas inside a gestation sac The patient came into hospital three months pregnant, with symptoms of threatened abortion The symptoms abated and she went out He saw her again 13 months after the presumed commencement of the pregnancy The whole of the front of the abdomen was perfectly dull A rectal examination was made and next day her temperature was 104° and the abdomen was very resonant An operation was performed and it was found that there had been a *primary rupture into the layers of the broad ligament and* the gestation sac had gone on developing There was an escape of very offensive gas on the sac being opened The patient made a good recovery and had had two children since The only explanation he had for the formation of the gas was that the bacillus coli communis had got into the gestation sac on account of the rectal examination —Dr RICHARD D PUREFOY said that most of them had seen the condition termed physometric in connexion with malignant disease or in cases of delayed or neglected labour where air had got *into the uterus The President s case was* remarkable on account of the gas having remained in the uterine cavity

Dr PUREFOY read a paper on two cases of Cystic Endometritis with Remarks on Treatment —Mr I HASTINGS TWEEDY said that cystic endometritis was a disease which he did not know personally and of which he could find no account He objected to fresh nomenclature and thought it better to adhere to the term glandular His objection to the term cystic was that it did not lead anyone to a knowledge of what was being dealt with, whilst glandular did —The PRESIDENT said that he divided endometritis into glandular and interstitial There were two kinds of glandular endometritis—hyperplastic and hypertrophic Hyperplastic endometritis was adenoma and in it there was an enormous increase in the number of glands Hypertrophic endometritis had a normal number of glands but they were greatly increased and distended and when occluded formed cysts The hyperplastic cases frequently became malignant therefore they had to be seen *often* and the uterus removed T[illegible] be merely distended tubes or if [illegible] ment was to remove the muc[illegible] and to try to cultivate a healthy mucous membrane His practice was to curette and to wash out once and to wash out again on the third and fourth day to see that nothing was left behind He used hot sterilised saline solution and did not employ any intra uterine medications

The PRESIDENT read a paper which indicated that Bossi s Dilator had not met with universal approval or adoption He was however convinced that within certain well defined limits it served a useful purpose He had employed it in four cases—three of eclampsia and one of placenta prævia—all of which were successful The entire time between the introduction of the dilator and the end of the third stage did not exceed one hour In the case of placenta prævia there was an extensive laceration of the cervix requiring stitches He considered Bossi s dilator to be dangerous when the cervix was long The close proximity of the uterine sinus added a new danger should the laceration unfortunately extend to or open them up —Dr KIDD said that one disadvantage of Bossi s dilator had been met by changing the number of blades from four to eight thus having eight points of pressure on the lower zone of the uterus and less probability of rupture Another objection was that the angle at which the dilator was set to the shaft was not the angle at which dilatation would take place Seigneux tried to meet this objection in his dilator but it had its disadvantages also —Dr FITZGIBBON said that he had used Bossi s dilator in a case in which he had induced labour at seven and a half months He commenced by using bougies but the uterus took on no action and they were introduced again on the following day The membranes had then ruptured and the

June, 1903, when clear fluid commenced to flow from the right nostril and very soon improvement set in, followed by complete recovery in the course of a few weeks.—Mr. F. C. LARKIN, Dr. R. CATON, Dr. W. B. WARRINGTON, Dr. F. A. GILL, Dr. R. J. M. BUCHANAN, Dr. J. HILL ABRAM, and Mr. W. THELWALL THOMAS discussed the case.

Dr. A. G. GULLAN read notes of two cases of Addison's Disease in which he had administered Suprarenal Extract. In the first case, that of a young man, in whom the symptoms of the disease were well marked, 15 grains of the extract were given thrice daily but with only temporary relief, the patient dying seven weeks later. At the post-mortem examination no signs of tubercle were found except in the suprarenal bodies which were both enlarged and destroyed by caseous masses evidently of a tuberculous nature. In the second case, that of a woman, the symptoms were less severe and she had benefited greatly by taking ·20 grains of the extract thrice daily.

Mr. DAMER HARRISSON opened a discussion on the Union of Nerves after Division He gave a short history of the subject, physiological and surgical. The more recent histological observations which support the theory of coalescence and the process of regeneration in the peripheral end of a divided nerve were described, together with the criticisms of Mott, Halliburton, and Edmunds. On the physiological side he advanced the view that the weight of evidence was on the side of the outgrowth theory and brought forward a series of observations made by himself and Professor F. Gotch after division and suture of the sciatic nerve in the rabbit which proved that sensation reflexes appeared first in the peripheral end nearest the point of suture and at later periods at the more distant points in the peripheral end. With regard to the motor response this appeared at an earlier date in proportion to the nearness of the division and suture to the muscles. These facts were difficult to explain by means of the coalescence theory and strongly supported the outgrowth theory.—Dr. ROBERT KENNEDY said that from the clinical point of view there was a well-established observation which the central theory of regeneration of nerves could not explain—namely, the early return of sensation after secondary suture of a divided nerve. Ranvier's view did not explain this rapid restoration, for, in the first place, unnaturally rapid growth of new nerve fibres from the central end would be required, as no sensation could be felt until the axis cylinders had reached the end organs. In the second place, there would be a difference of time in the reappearance of sensation accordingly as the section of the nerve was near or far removed from the end organs, which there was not. As regards suture of the nerve immediately after section, sensation took much longer to appear, and this was what would be expected, as time was required for regeneration of the new fibres in the distal segment. When suture was performed at a time remote from section the distal segment had had time to form its new nerve fibres. The only difficulty was to explain the very early passage of impulses across the plane of suture, but this was probably brought about by the junction of neurilemma cells newly formed from the central and peripheral ends, the gap being thus bridged, the impulses apparently having the power to pass along the protoplasm of such cells. The reason why motion recovered later than sensation was owing to the rapid degeneration of the muscles after nerve section, which degeneration must first be recovered from. From observations made in the past few years Dr. Kennedy was of opinion that muscular tissue never completely degenerated, although separated from the nerve centres for long periods. A series of microphotographs were shown illustrating his views of nerve regeneration in the distal segment as opposed to the recent explanation advanced by Langley and Anderson.—Professor C. S. Dr. R. A. FLEMING read a paper on Massage, Passi
Movements, and Modified Resisted Exercises in the Treatme
of Advanced Cardiac Dilatation, in which rest and cardi
tonics had failed to yield further benefit. He thought th
the exercises gave tone to the heart where it was possible fo
the myocardium to respond at all and they probably did s
by dilating the vessels and relieving the over-burdened heart
Careful percussion of the cardiac right and left borders, taken along with the position of the apex beat, yielded accurate data as to the contraction of a dilated heart. The method of treatment consisted in successive periods of daily massage, followed from seven to ten days later by passive movements of the arms and legs and after other seven to ten days by resisted exercises. The patient was not allowed out of bed during the period of from 21 to 30 days and the exercises were limited, therefore, to those which could be performed in bed. Clinical details were given of ten cases, two of which were cases of aortic and mitral incompetence and in neither of these two was the treatment successful. In the remaining eight cases success followed the treatment, the patients were allowed up after the period of resisted exercises was finished and were made to walk slowly for a few minutes, and the period of active exercise thus taken was gradually lengthened

the menses occurred regularly during the early months of extra-uterine gestation.—Mr. Malcolm replied to Dr. Sunderland by saying that he was quite sure that menstruation was not always in abeyance until the tube ruptured.—Dr. F. J. McCann delivered an address (illustrated by a large series of lantern slides) on the Early Diagnosis of Cancer of the Neck of the Womb. A short description was given of the normal anatomy of the cervix and the importance of the "transitional area" (i.e., where the squamous epithelium covering the vaginal portion joined

advent of ulceration altered the relationship of the different parts of the cervix. Three clinical types of cancer of the vaginal portion of the cervix occurred. 1. The papillomatous or polypoid type, where a sprouting growth extending upwards into the vaginal canal originated by a somewhat broad base from the margin of the external os uteri. In this class was included the so-called cauliflower excrescence. 2. The infiltrating type, where the tissue of the vaginal portion was infiltrated with cancerous growth, one or both lips of the cervix being affected. 3. The superficial flattened type prone to early ulceration. Here the growth crept over the surface of the vaginal portion, and as there was a tendency to early ulceration a true malignant ulcer in an early stage was seen. Two special types of cancer affecting the cervix proper might be identified: (1) superficial carcinoma of the mucous membrane of the cervix proper, characterised by the growth of papillomatous masses of different sizes in the interior of the canal, followed later by ulcerative changes which hollow out the cervix and produce the characteristic crateriform ulcer; and (2) the infiltrating type where the walls of the cervix were infiltrated in part or in their entirety with cancer. This last type tended to spread rapidly to the lymphatics and hence was frequently discovered when it was beyond hope of eradication. The early signs of cancerous disease were discharge and hæmorrhage. Discharge was the first sign but hæmorrhage was the sign which prompted the patient to seek advice. It would be found that careful inquiry into the history of early cases would elicit the fact that an alteration in the quality and quantity of the leucorrhœal discharge was observed before any bleeding had occurred. For this reason all cases of discharges or atypical bleeding should be carefully examined and the os uteri inspected through a speculum. The signs elicited on examination were as follows: (1) friability, a sign of great importance which could be tested by the finger nail, the curette, the uterine sound, or a long probe; if there be much fibrous tissue present in the growth friability may be entirely absent; (2) the occurrence of bleeding, the amount of which was entirely out of proportion to the extent of the injury inflicted; and (3) the definite occurrence of new growths from the surface of the cervix, from the lining of the cervical canal, or in the substance of the cervix.
changes in the cervix which
were as follows. 1. Erosion.
was no ulceration. It surrounded the os externum; the edge was not sharply defined but faded away into the surrounding mucous membrane. Epithelial islets and plugged follicles might be noted on the surface and there was no infiltration of the base. 2. Chronic

On withdrawing the finger blood might be seen upon it. Per speculum the mucosa of the cervix was smooth, shining, bright red, with total absence of any ulceration It was only by firm pressure of the finger or the sound that bleeding from the surface occurred, and, above all, neither the sound nor the sharp curette could detach pieces from the cervical lining. If still in doubt the microscope could be used. A full description was given of the different varieties of ulcer met with in the cervix. The differential diagnosis from
'ended follicles, &c., was given.
inted out that one of the most
cancer was the presence of
sues.—Mr. Donald J. Armour asked Dr. McCann whether in cancer of the vaginal portion of the cervix he always performed a panhysterectomy or was satisfied with supravaginal amputation.—Mr. Cecil H. Leaf wished to know Dr. McCann's opinion as to how much importance he attached to the presence of ulceration, as he did not consider it a trustworthy guide.—Dr. McCann emphasised Dr. Robinson's remarks as to the importance of friability being an early sign. In reply to Mr. Armour, he said that he was still in favour of supravaginal amputation of the cervix in early cases of cancer affecting the vaginal portion, whilst he preferred hysterectomy for other forms. In replying to Mr. Leaf he said that apart from traumatism a genuine ulcer of the cervix was malignant, tuberculous, or syphilitic, and as the last two were rare cancer should be suspected.

FORFARSHIRE MEDICAL ASSOCIATION.—A meeting of this society was held in the Royal Infirmary, Arbroath, on Jan. 18th, Dr. Andrew Key, the President, being in the chair.—Dr. A. D. Yule read a paper on Some Symptoms and Sequelæ of Pyloric and Duodenal Ulcers. He referred specially to dilatation of the stomach as a sequel and gave particulars of two cases of excessive gastric dilatation due to obstruction produced by cicatrisation of ulcers near the pylorus. Medical treatment had no effect but complete recovery followed the operation of posterior gastro-jejunostomy performed by Mr. D. M. Greig. Notes were also read of the case of a woman, aged 42 years, who for many years had all the classical signs and symptoms of a gastric ulcer near the pylorus and whose persistent pain and frequent vomiting were not improved by medical treatment but were abolished by an exploratory laparotomy at which no evidence of any old or existing ulcer was found. Mr. Greig was again the operator and pyloroplasty was performed as there were moderate dilatation of the stomach and some degree of hypertrophy of the circular muscular fibres of the pylorus. Three months after the operation, however, the persistent pain, with exacerbations and occasional vomiting, returned. The case was most probably one of neurasthenia and it was considered that further surgical measures did not hold out much hope of permanent benefit.—Mr. Greig then read notes on a series of cases of Suprapubic Prostatectomy for Senile Enlargement. He pointed out that it was a mistake to consider the prostate as a trilobed organ, for it only became such as the result of pathological changes as in the hypertrophy of old age. He described the method of operation and indications for surgical intervention in over-distension of the bladder and showed specimens from ten operations.—Various cases were shown by Dr. W. J. Dewar, Dr. J. D. Gilruth, Dr. D. Laing, and Dr. J. D. Duncan.——A meeting of the society was held in the School of Medicine, Dundee, on Feb. 2nd, Dr. J. Rorie being in the chair.—Dr. W. E. Foggie read notes of a report on the Incidence of Rickets amongst the children who had attended the medical out-patient department of the Dundee Royal Infirmary during the past year when he was in attendance two days during each week. Amongst 463 children examined beading of the ribs was present in 75 per cent. and enlargement of the wrists in 23·3 per cent. The percentage of changes in the shape of the chest and of the long bones was but small. Though rickets was thus widely spread the type of the disease did not seem a very severe one, this being proved by the fact that "flat pelvis" was not met with to any great extent in obstetrical practice.—Dr. J. S. Y. Rogers read notes on three cases of Infective Arthritis occurring after Influenza. He remarked that the literature on the subject was very meagre but the subject was worthy of further investigation. The cases were similar in that all were influenza of the gastro-intestinal type and several other persons in the same three households as the patients were affected. The first and second cases were those

with considerable swelling
nd showed every sign of
t reveal any pus but a
nined fluid escaped with

pieces of necrosed tissue. This was examined bacteriologically but the result was negative. The patient made a good recovery but very considerable stiffness remained in the joint. Dr. Rogers considered that there were two distinct forms of infective arthritis. The first variety was seen in typhoid fever and scarlet fever where a swelling of the large joints simulating acute rheumatism might take place. This condition passed off in a few days and did not go on to suppuration. In the second variety there was implication of one joint only which might be of the four following types: (1) slight transient swelling and effusion; (2) considerable effusion, which was at first turbid and then might be purulent: (3) involvement of the peri-articular tissues, with brawny swelling and reddening of the skin, suggesting suppuration; and (4) early suppuration, a destructive arthritis. The first variety might be due to the action of the specific micro-organism. The second variety was probably due to the action of ordinary bacteria of suppuration. The prognosis depended on the type of the disease. The first three types were favourable with regard to recovery, though there might be considerable stiffness of the joint following. In the fourth type the prognosis was very unfavourable, as a great many ended fatally within a short time.—Dr. J. Mackie Whyte showed a Placenta having Numerous Tubercles on the Amniotic Surface. The woman suffered from pulmonary tuberculosis of five years' duration.—Various patients were shown by Dr. E. F. M. Neave and Dr. Foggie.

EDINBURGH OBSTETRICAL SOCIETY.—A meeting of this society was held on Feb. 8th, Sir J. Halliday Croom, Vice-President, being in the chair.—Dr. F. W. N. Haultain read a paper on a Clinical and Pathological Analysis of a Successive Series of 120 Abdominal Hysterectomies for Fibro-myomata. The operation was performed in 85 for bleeding, in 15 for size, in 13 for severe pressure symptoms, in 2 for reflex symptoms, in 3 for dysmenorrhœa, and in 2 for constant pain. The ages of the patients were in 2 cases between 20 and 30 years, in 28 between 30 and 40 years, in 80 between 40 and 50 years, in 8 between 50 and 60 years, and in 2 over 60 years. Of the eight cases between 50 and 60 years only one had reached the climacteric. The severe pressure symptoms included three cases of retention of urine, one case of cramp in the legs, and one of pressure on prolapsed ovaries. Reflex symptoms were illustrated by a case of violent laryngismus stridulus and one of persistent vomiting, both cured by the operation. The effect of fibroids on child-bearing was shown thus: of the 120 cases 71 were married and of these 42 were absolutely sterile and the remaining 29 had an aggregate of 78 children. But the average age of the youngest child before the patient was operated on was nine years; this proved convincingly that fibroids had a sterilising effect on the patient. Dr. Haultain tabulated the pathological characters of the fibro-myomata as follows:—1. Of the uterine body.—Simple fibro-myomata, 63: (*a*) multiple, 54; and (*b*) single, 9. Degenerated, 20: (*a*) œdematous, 12; (*b*) red degeneration or infarction, 1; (*c*) cystic, 2; (*d*) calcified, 1; (*e*) sarcomatous, 2; (*f*) teleangiectatic, 1; and (*g*) diffuse nodular fibrosis, 1. Complicated with other growths, 24: (*a*) adeno-carcinoma of the body, 5; (*b*) mucous polypi, 9; (*c*) cystic ovarian tumours, 6; (*d*) solid ovarian, 1; and (*e*) broad ligament cyst, 3. Complicated with pregnancy, 3. Complicated with marked ascites, 1. 2. Of the cervix, 7: (*a*) single, 6; and (*b*) multiple, 1. 3. Of the body and cervix combined, 2. The hard and slow growing were mainly fibrous, while the soft rapidly growing had a large proportion of muscle in their composition. The blood-vessels had a primitive character of the nature of sinuses, producing thus a sluggish circulation in the growth and predisposing to secondary changes. Of the three cases associated with pregnancy, hysterectomy was performed in one case at the third month, and in the other two at the fourth month. The reason for operation in two cases was severe continuous pain and pressure symptoms. Unless urgent symptoms manifested themselves pregnancy should, in the majority of cases, be allowed to continue, but if interference became necessary hysterectomy was preferable to the production of abortion. The method of operation was the sub-total or supravaginal in 105 cases and panhysterectomy in 15 cases owing to cervical involvement or associated malignancy. Dr. Haultain's preference for the supravaginal method was due almost entirely to the fact that it was simpler to perform and thus quicker and safer. The supporters of the pan operation referred to a possible chance of a subsequent malignant growth forming in the cervix; but the chance of this was infinitesimal. In operating, Dr. Haultain first clamped the vessels and after removal of the tumour tied them. He left the cervical stump as it was cut, not making any flaps to cover over the raw surface; the cervical canal acted as a drain. The layers of the broad ligament were carefully apposed by continuous silk sutures. He preferred sponges to swabs; they were softer and kindlier to the peritoneum, were more absorbent, and were more easily counted. He prepared them with a very strong solution of carbonate of soda and afterwards kept them in carbolic lotion. During the operation they were washed in cold and then placed in hot sterile water. He used the through-and-through method of stitching the abdominal wound and with silkworm gut. The patient was in the Trendelenburg position during the operation. The patient after the operation was permitted to lie in any position in which she might feel most comfortable. After the chloroform sickness tea, soups, and liquid nourishment were given. The bowels were moved on the third day, after which a plain diet was allowed according to fancy. Three of the 120 cases died. One never rallied after the operation (supravaginal) owing to her extreme anæmia. The other two died after the pan operation from sepsis; one the result of the infection of the tumour bed by the bacillus coli through the bared rectum, from which the large posterior cervical fibroid was separated, and the other was due to peritoneal infection from a sloughing growth involving both body and cervix uteri. In all cases of subperitoneal and interstitial fibroids which gave rise to symptoms and reduced a patient's health and comfort, hysterectomy should be performed if she was under 45 years of age. Hysterectomy should be performed at any age when the symptoms were urgent if myomectomy could not readily be performed. If no symptoms were present then no treatment was necessary and it was unwise to acquaint the patient of the presence of the tumour.—Dr. J. Haig Ferguson, Dr. J. M. Munro Kerr (Glasgow), Dr. J. W. Ballantyne, Dr. S. Macvie, Dr. J. B. Hellier (Leeds), Dr. W. Fordyce, Dr. J. L. Lackie, Dr. M. Campbell, Dr. J. Ritchie, and Sir Halliday Croom discussed the paper and Dr. Haultain replied.

HARVEIAN SOCIETY OF LONDON.—A meeting of this society was held on Feb. 9th, at which Dr. G. A. Sutherland read a paper on Lobar Pneumonia in Children. He referred to the valuable information to be obtained by a study of the child's expression and breathing. The expression of the face was much more placid in lobar pneumonia than in catarrhal pneumonia owing to the obstructive conditions present in the latter. The breathing in lobar pneumonia was rapid, superficial, and often of inverted respiratory type. The increased movement of the alæ nasi usually consisted of an expiratory and not an inspiratory dilatation and was due to forcible expiration. He reviewed the clinical symptoms of three leading types of pneumonia—the cerebral, the gastro-intestinal, and the renal—in which all through the disease the pulmonary condition might remain unsuspected. Renal cases might present as the leading symptom hæmaturia or general dropsy. The treatment in ordinary cases was practically that of a specific fever. Coughing, fever, sleeplessness, and pain were symptoms which might call for treatment. As a rule the pre-critical stage was the period of greatest severity and cardiac tonics and leeching were the best remedies at this time.—Dr. Guthrie thought that lobar pneumonia was better recognised now, being less fatal than broncho-pneumonia. He thought that the fa [illegible] not apathetic and placid, the breath being [illegible] He believed that central pneumonia with distant tubular breathing occasionally occurred. He remarked on [illegible] should be pushed where required. [illegible] thought that the expression was mostly anxious. [illegible] when given should be started early in the disease. Empyema was more common after lobar pneumonia than after the catarrhal form.—Dr. A. Morison thought that the fever should be treated if high and not allowed to run riot as it affected the circulatory system. Ice to the head was soothing and a useful antipyretic. Bleeding was at times useful at the onset. He also thought that strychnine was a drug that should be pushed when needed. Digitalis he did not use. Turpentine was useful when there was much secretion in the tubes —Dr E Cautley was accustomed to differentiate between children and infants in speaking of pneumonia in childhood The possibility of otitis media as a complication, often unaccompanied with pain, should always be remembered Bleeding in children was rarely necessary and he doubted the advantage of using the ice bag —Dr Sutherland replied —Mr E Laming Evans read a paper on Anterior Metatarsalgia with notes on seven cases An analysis of these seven cases showed that the fourth metatarso phalangeal joint was affected in all and the third in two cases All the cases occurred in women, six in private and one in hospital practice in this agreeing with all previous records No injury, or sudden onset, or rupture of the transverse ligament, was present The longitudinal arch was depressed in three cases and the transverse arch in three The fashionable narrow pointed shoe was considered to be responsible for an aggravation of the mischief, if not the actual cause of it Five of these cases had been dealt with by palliative measures, with partial relief of the symptoms and two by excision of the head and the neck of the fourth metatarsal bone with complete removal of the pain and with a sound functional foot, without any weakening Mr Evans advocated that palliative measures should be tried in the first instance, but if these failed, that removal of the head of the metatarsal bone should be performed with a good chance of removing the disease and without fear of weakening the foot —Mr J Jackson Clarke had not operated on these cases during the last five years The general health should be improved and much attention paid to shoes He advocated the use of steel plates in the boots carefully made after taking a plaster mould or model of the foot Metatarsalgia was often a symptom of flat foot Patients were often markedly irritable with this condition

Society of Medical Officers of Health —A meeting of this society was held on Feb 10th, Dr J F J Sykes the President being in the chair —Dr G F McCleary read a paper on the Reform of the Milk supply, in which he urged its municipalisation on the lines suggested by Dr Edmund Cautley and Mr Lawson Dodd or by Dr W Leslie Mackenzie Sanitary progress during the nineteenth century had been mainly concerned with civic cleanliness, sewerage, scavenging, house construction, and water supply, but of late personal cleanliness or hygiene had been attracting attention in the control of food supplies infectious diseases, overcrowding, and like questions Few of these were of greater importance than that of the milk supply, which, as Dr A Newsholme had shown was answerable for a large part of infant and child mortality, directly or indirectly The conditions under which milk was produced, conveyed and distributed were for the most part defective and antiquated when not actually filthy and dangerous The rural sanitary authorities on whom devolved the duty of inspecting the cowsheds were apathetic, if not worse and the county councils were little better Only by acquiring powers to extend their activities beyond their boundaries could the urban authorities protect the interests of the great majority of the consumers This had been done on the largest scale in the matter of water supply and on more restricted lines in respect of sewerage works isolation hospitals, &c The corporation of Manchester had through the efforts of Dr James Niven obtained powers under the milk clauses of a local Act which had proved of great value But inspection could do no more than prescribe prohibit and prosecute it could regulate but could not alter character habit economic conditions and in each of these, from the cowshed in the country and the cowman s cottage to the shop and trolley in town there was need of radical change He wished to see cowsheds abolished and milk drawn by clean men into clean vessels and after being chilled sent up and sold in clean stoppered bottles without any rise in price This could be achieved only by the entire control and if possible the production of the milk supply being entrusted to municipal councils or elective boards having exclusive privileges over certain districts, as was the case with sewerage and drainage and the supply of gas water, and electricity, or if that were found impracticable they might open model dairy farms and milk shops which should serve as object lessons to others This however, would not meet the difficulty of the price of milk which in any industry conducted for profit must be affected by a serious increase in the cost of production —Dr Philip Boobbyer took a practical interest in the milk question and was in favour of a progressive policy when he could see a limit or a goal, but municipal indebtedness had reached such vast dimensions that they ought to consider seriously proposals for embarking on undertakings that could, even though less perfectly, be carried on by private enterprise, and it was not politic to do so at a loss throwing the burden on the ratepayer One large borough had suspended *sine die* the scheme for an abattoir for which the estimates had been obtained and the site secured on account of the cost £25 000 —Mr J Sadler (secretary of the Cheshire Milk Supply Association) pointed out that the conditions of the production of milk in scattered farms over wide areas were totally different from those of the manufacture of gas or generation of electricity in large central buildings Reform should be directed to the education of all engaged in the work, the cooperation of farmers collectors and dealers and stricter supervision of the carriage provided by the railways The local authorities should enforce the Cowshed and Dairies Orders, throwing the responsibility and expenses on the owner rather than the occupier —Mr J Nugent Harris (secretary of the Agricultural Organisation Association) testified to the good effects of education, moral suasion and cooperation and said that to obtain clean milk our farmers should treat their cows with the same individual attention that they gave to their horses —Mr J Tubb Thomas and others deprecated municipal action while several gentlemen mostly visitors, defended it urging against collection by companies the difficulty of tracing the source of epidemics when milks from many farms were mixed —Dr E F Willoughby, speaking from an experience of 20 years condemned municipalisation as futile and impracticable He entirely agreed with Mr Harris and Mr Sadler These and other speakers had shown them what improvement could be brought about by strict inspection under existing conditions

Glasgow Pathological and Clinical Society —A meeting of this society was held on Feb 13th, Professor R Muir the President, being in the chair —Dr John Anderson showed as a fresh specimen an Abscess of the Brain accompanied by leptomeningitis due to the pneumococcus —Dr J Lindsay Steven showed a girl aged two years suffering from Enlargement of the Spleen and the Liver possibly Splenic Anæmia The illness was of eight months duration The enlargement of the liver and the spleen was considerable The blood condition was similar to that seen in the splenic anæmia of adults red corpuscles 3 900 000 hæmoglobin 35 per cent, leucopenia (about 2000) with relative decrease of the polymorphonuclears There were no symptoms of ill health except irritability the child being fairly well nourished not anæmic and not jaundiced There was no enlargement of the lymphatic glands Another member of the family had died after a similar illness —Dr J Crawford Renton showed or read notes of a series of cases (1) A case of Cholecystenterostomy, (2) cases of Excision of the Elbow joint to remedy the effects of a fracture in the neighbourhood, (3) a case of Kader s Gastrostomy for œsophageal stricture (4) a case of Laminectomy for paralysis of the legs due to tuberculous disease of the vertebræ, and (5) demonstrat

—Dr J Kerr Love and Dr J

Intrathoracic Tumour and sh

of the growths In Case 1 the first symptom was pleurisy, then hoarseness cough and muco purulent sputum developed, later hæmoptysis and paralysis of the left vocal cord The growth involved nearly the whole of the left pleural sac and there were large masses in the left lung, there was very little mediastinal extension Microscopically it presented the characters of an endothelioma and Dr Love and Dr Leitch were of opinion that it had originated from the pleura The patient was a man aged 32 years In Case 2 the principal sign of disease was pain and swelling of the left arm supposed to be due to thrombosis Latterly extreme dyspnœa developed The growth was a small spindle celled sarcoma It was situated in the mediastinum in front of the trachea and for the most part above the bifurcation It had extended round, and was invading the walls of the trachea The patient was a woman aged 46 years —Dr W S Syme read notes of a case of Tumour ("Carcino sarcoma) of the Thyroid and Dr M Logan Taylor described the histological characters of the growth In parts the tumour presented the characters of a scirrhous carcinoma, in other parts it appeared to be a mixed-celled sarcoma and where these met the two types of tumour overlapped and intermingled, producing the effect of a scirrhous carcinoma, the connective tissue stroma of which was undergoing sarcomatous development, which was destroying the carcinoma. The tumour was very curious and puzzling. The case would be reported in full detail.—Dr. G. H. Edington showed: (1) specimens of Ribs showing different Degrees of Thickening from cases of Chronic Empyema; (2) a Large Epulis from the Upper Jaw; and (3) a Parotid Mixed Tumour.—Dr. Edington also showed Photographs of cases of Carcinoma of the Mamma.—Dr. Anderson showed: (1) a Sarcoma of the Male Breast with recurrences; (2) a Malignant Cystoma (Papillomatous) of the Kidney, with microscopic sections of both as card specimens.

Medico-Legal Society.—A meeting of this society was held on Feb. 14th, Dr. W. Wynn Westcott being in the chair.—Dr. A. G. Bateman of the Medical Defence Union opened a discussion on Privileged Communications and Professional Secrecy. Many certificates of health and of death were open to the public gaze; the privacy of the chamber of death was not respected by the press; indeed, our law courts to-day would not allow *the oath of Hippocrates as a plea for secrecy. Judges at nisi prius* trials had differed as to the rights and duties of medical witnesses. Personally he advised the exposure of crime when it was discovered, even during professional attendance. Detailed consideration was given to the demands of employers to know the result of the medical examination of employés; the reports of medical officers upon the conduct of subordinates (such documents should be brief and unadorned); and the clinical jurisprudence of cases of suspected poisoning. After citing many actual illustrations Dr. Bateman suggested the following points as pertinent to the discussion: Can a medical man obtain the same measure of protection as a lawyer and, if so, is it for the public benefit? Given, for example, a case of abortion, should the public authorities be informed, or would such information be "an act of monstrous cruelty"? If he held his peace would he be concealing a felony and hence liable as *particeps criminis?* Should not Parliamentary powers be obtained whereby death certificates would become confidential documents?—Dr. Westcott claimed that a man should have as much secrecy as he desired during life and after death as much as his representatives wished.—Sir Thomas Stevenson held that secrecy should be strictly kept; medical men, clergymen, and also lawyers should, however, "tell what they know" in the witness-box.—Dr. John Glaister discussed the position of the "hostile" medical witness; a medical man should never initiate criminal proceedings; in court he should demand a definition of his rights and duties as a witness; he should forewarn those whose bodies he examined of the possible adverse consequences and supply both sides in criminal trials with identical reports.—Dr. F. J. Wethered tested the rules with several examples.—Dr. W. P. Herringham noted that both the ethics and the law on the subject varied from time to time; in some cases (e.g., venereal infections) it might be necessary to break the rule of secrecy.—Dr. J. G. Garson saw the need of a public official who might be taken into the confidence of medical men when in doubt as to a point of clinical jurisprudence.—Mr. A. D. Cowburn, Dr. M. Greenwood, Miss E. L. C. Appel, M.B., Mr. D. Cotes-Preedy, and Dr. S. B. Atkinson having spoken, Mr. Walter Schröder stated that it was very rare for coroners to demand preliminary information from medical men, it was usually volunteered, otherwise the facts were revealed at an inquest.

Midland Medical Society.—A meeting of this society was held at Birmingham on Feb. 15th, Dr. E. W. Wood White, the President, being in the chair.—Dr. J. G. Emanuel showed an infant, six weeks old, suffering from Paralysis of both Arms caused at birth. The mother was a primipara, aged 32 years. The child was full term, the pelvis was a little contracted, and the head presented. The accoucheur, failing to deliver with forceps, turned and delivered the trunk, the shoulders, and the arms without difficulty. The after-coming head, however, became impacted and great force was expended in its delivery by pulling on the trunk with the help of a towel wrapped round the shoulders. The day after birth complete paralysis of both upper limbs was noted. Two weeks later movements in the fingers of the left hand were observed. A month later the left arm showed typically the condition seen in Duchenne's birth paralysis as a result of rupture of the fifth and sixth cords of the brachial plexus, but the right extremity had undergone no improvement and evidently the brachial plexus on this side was severely damaged. Mr. L. P. Gamgee proposed to wait till the infant was two months old and then if the right arm still showed no improvement to attempt suture of the divided cords of the plexus.—Dr. J. Douglas Stanley showed a case of Subsiding Tuberculosis.—Dr. Thomas Wilson showed: (1) A specimen of Cancer of the Cervix Uteri with Pyometra; and (2) a specimen from a case of Tubal Gestation showing an oval enlargemt of the broad ligament due to hæmorrhage into an early ovum; the tube was continued over the surface of the hæmatoma, from which its lumen was free.—Mr. W. Billington read a paper on Some Points in the Treatment of Tuberculous Disease of the Hip.

Reviews and Notices of Books.

Mental Defectives; their History, Treatment, and Training. By Martin W. Barr, M.D., Chief Physician, Pennsylvania Training School for Feeble-minded Children, Elwyn, Pennsylvania. London: Rebman, Limited. 1904. Pp. 368. Price 17*s.* 6*d.* net.

This work, the preface informs us, "addresses itself primarily to anxious parents and earnest teachers rather than to the scientist." The author observes that he has not dwelt at any length on the stigmata of degeneration. This topic cannot be said to be dealt with at all, in point of fact and for this omission no explanation is given. The historical survey of the subject treated is instructive, a good account being given of the rise and development in various countries of the modern system of care and training of the feeble-minded. This is followed by as complete a list as possible of the principal institutions for mental defectives in all countries providing such. The need for larger provision in most of these (including our own), if not in all, is apparent. Passing to classification the usual etiological, pathological, and physiognomical (ethnological) groupings are mentioned, but the author eschews them, and we think wisely, for they contain much that is pretentious, illogical, and unscientific. Since the ideal, or pathological, classification is impossible in the present state of our knowledge it appears to us of no great moment what the basis of classification may be provided that the scheme followed be consistent. The London School Board has adopted a simple educational classification in the medical examination of children for its special schools and Dr. Barr follows the same principle though on a more elaborate scale. He describes idiots and idio-imbeciles—a low-level class requiring asylum care; imbeciles, including moral imbeciles, of different grades, trainable in various (some in high) degrees but requiring perpetual guardianship; and backward or mentally feeble, capable of being trained for a place in the world.

The question of etiology is dealt with on a basis of 2380 cases collected by Beach and Shuttleworth in England and 3050 cases compiled by the author, chiefly from the records of the Pennsylvania Training School, a total of 5430 cases. The immense preponderance of ante-natal causes of mental defect is manifest. This both English and American tables show but the reader is struck by the difference in importance assigned to individual ante-natal causes in the two. Thus, taking the tables in the order mentioned the following are the percentage occurrences of certain causes: family history of pulmonary tuberculosis, 28·31, against 7·57; of insanity, 16·47, against 7·08; and of intemperance, 16·38, against 4·46; abnormal condition of mother during gestation, *29·87, against 8·49. As regards causes acting at birth,* whilst the English table assigns 14·24 per cent. of cases *to* protracted pressure the American has only 0·59 per cent. due to difficult labour. Again, in post-natal causes there is great discrepancy as to epilepsy and eclampsia, the English table giving these in 35·5 per cent. and the American in 5·90. On inquiry into these great discrepancies it is clear to us that they must be due to different methods of dealing with the etiological factors. Whereas the English table states the number of times an individual cause was recorded, thus giving a preponderance of causes over cases, the American evidently assigns one cause and no more to each case. We fail to see how percentage results are comparable in these circumstances.

The figures of many authorities are quoted as upholding the usual teaching that consanguinity is not harmful except as intensifying bad heredity common to both parents. Syphilis as a factor is shown to be unimportant. In a chapter on Diagnosis due attention is given to the important subject of early recognition of indications of mental defect. A useful table of death-periods based on 625 deaths shows the largest mortality to occur between the tenth and the twenty-fifth years. 50 pages are devoted to training, mental and physical, and treatment. Speaking of trainable defectives Dr. Barr says that the consensus of opinion is that training at an earlier period than the seventh year is likely to prove disastrous. He considers that the limit of receptivity rarely extends beyond the sixteenth year. The importance of special school training for the backward, on the borderland of deterioration, is emphasised. It is stated that defective vision is noticeable in 90 per cent. of the high and middle grades of imbeciles. The futility of craniectomy, which is well known to be based upon a false pathological conception, is shown and perhaps the demonstration scarcely needed seven pages.

There is a short chapter on "asexualisation" of the mentally defective. It appears that a circular was sent from Elwyn to the heads of 61 institutions for mental defectives in America and abroad requesting an expression of opinion on this subject, including an opinion as to the kind of operations desirable and as to the propriety of legalising operations. Only 12 replies were received and of these only nine were explicit. All agreed that procreation was inadvisable and a majority considered that legislative aid should be sought. A memorial on this subject addressed to the Senate and the House of Representatives of Pennsylvania, and signed amongst others by the author, was followed by an Act which passed both Houses authorising operation for the prevention of procreation in non-improvable idiots and imbeciles in institution care and under safeguards. This Act was returned by the Governor "for some trifling technicality" and was lost and failed to become law. An account is given of the performance of operations for "asexualisation" in certain institutions for the feeble-minded in the United States.

Short chapters are devoted to cretinism, microcephalus, and hydrocephalus. Epilepsy, pure and simple, and Jacksonian epilepsy have a chapter, though whether these subjects are suitable for inclusion in a work of this sort may be doubted. The author considers that the epileptic "may be brought to recognise that with some assistance outside himself he may avert or defer an attack, and that therefore it is in a measure under his own control." Thus he is able "at theatrical entertainments to exact promises from epileptics that there shall be no spasms during the performance, and the evening always passes without such interruption, the attention being diverted, whilst the will is *unconsciously* [the italics are ours] exerted and centred on one aim with definite result." The greater part (65 pages) of the rest of the book is taken up with illustrative cases. There are 53 full-page plates of excellent illustrations of all kinds of mental defectives and a good list of works on the subject closes the treatise.

Dr. Barr writes from an experience of almost 20 years in his subject and this fact lends weight to his views. The wisdom of writing books for "anxious parents" may be doubted. But the "earnest teacher," who is also addressed in this work, will, we think, derive benefit from its study.

Lectures on Diseases of Children. By ROBERT HUTCHISON, M.D. Edin., F.R.C.P. Lond., Assistant Physician to the London Hospital and to the Hospital for Sick Children, Great Ormond-street. London: Edward Arnold. 1904. Pp. 338. Price 6*s.*

THESE lectures have already been published in the *Clinical Journal.* Of the importance of the subject there can be no question but the author scarcely does justice to the ordinary qualifying examinations when he says in his opening lecture that they make no demand for a special knowledge of the diseases of children. A cursory glance at examination papers or a casual visit to any of the *vivâ-voce* examinations should have convinced him that those responsible are fully alive to the need for stimulating the study of this branch of medicine.

The volume is composed of nineteen lectures and in these the author has endeavoured to fill some of the gaps which are, in his opinion, left in ordinary teaching in the wards. The first lecture deals with the clinical examination of sick children and the details are full of practical hints. Every practitioner has learnt the importance of delaying percussion to the end of the examination but it is well that students should here be warned against percussing before auscultating. Concerning the artificial feeding of infants stress is laid upon the perils of rapid changes from one kind of food to another and there is a valuable analysis of the infant foods at present in use. Regarding the employment of starchy food the directions are somewhat vague and it is to be regretted that the age of the infant who thrived with "a considerable quantity of cornflour" (p. 42) is not given. The next two lectures are devoted to the digestive disorders of infancy, colic, vomiting, and diarrhœa, and in these due stress is laid upon washing out the stomach and the colon and upon the subcutaneous injections of fluids.

Marasmus, congenital syphilis, and tuberculosis in childhood form the prelude to an interesting lecture on Rickets, a subject which appears to possess a peculiar fascination for all who write or speak of diseases of children. Probably all who practise among children are struck with pity for the innocent sufferers from this preventable disease and are cheered by the extremely satisfactory results of treatment, while the cases are so numerous that it is impossible for anyone lecturing upon rickets to employ the vague terms so often necessitated when dealing with rare diseases and with secondhand information. The account here given is vivid and the subject is illustrated by several admirable reproductions of photographs. Infantile scurvy is next dealt with, Dr. Hutchison expressing an opinion that this term should replace that of "scurvy rickets." It is rather surprising, in a book characterised by dogmatism, to find the author repeatedly recommending "recourse to the therapeutic test." Concerning rheumatism in childhood much that is of interest is to be found in these pages, though many will demur at the somewhat loose pathology indicated in the comparison of rheumatic nodules in the skin and the vegetations to be found on the mitral valve. Considerations of space seem to have influenced the lecture on the Respiratory Diseases of Children, while the range of subjects touched upon under the heading of "Some Functional Nervous Diseases of Children" is also too wide for adequate treatment. The lectures on the Paralysis of Childhood and upon Meningitis are far more complete and the hints for diagnosis are likely to be very serviceable. The varieties of mental deficiency are carefully classified, the differences between cretins and Mongols, of the microcephalic, hydrocephalic and paralytic groups, together with other varieties, being duly dealt with. One of the concluding lectures is devoted to the varieties of anæmia and here the author once more presents a rather overcrowded picture. It is obviously difficult to compress into one lecture all that is worth knowing about the following subjects: (1) Congenital abnormalities of the blood; (2) primary anæmias—e.g., pernicious anæmia and chlorosis; (3) secondary anæmias: (4) anæmia associated with enlarged spleen: (5) leukæmias: and (6) affections of the adenoid tissue. The diagnostic significance of some common symptoms of disease in children is approached in a lighter vein and with reference to illustrative cases. The subject readily lends itself to this treatment though it necessarily leads to a certain repetition of material contained in the earlier lectures. The same remark holds good for the concluding lecture on some medical aspects of adenoid vegetations in infancy and childhood.

From the foregoing remarks it will be gathered that within the scope of these lectures Dr. Hutchison has succeeded in imparting a great deal of information which should stimulate further inquiry and study. He has been hampered by the difficulty, inseparable from lectures, of dividing his material into sections which fill out the allotted time, and as the diction of the lecture is retained the style is perhaps more personal and dogmatic than is customary. Reference has already been made to the illustrations; these are of unusual excellence and the 52, with one or two exceptions, are from photographs of the author's cases.

Anatomie des Membres: Dissection; Anatomie Topographique. (Anatomy of the Limbs: Dissection and Description.) By Dr. CH. DUJARIER, late Prosector in the Dissecting Room of Clamart, Director of Surgical Clinique at the Faculty. With 58 original plates by REGNIER. Paris: G. Steinheil. 1905. Pp. 304. Price 15 francs.

THIS work is the fruit of Dr. Dujarier's term of prosectorship in the dissecting room at Clamart and is intended as a practical guide to students in their dissections. The illustrative plates have been prepared under the author's supervision from his own dissections; they are mostly from normal subjects but there has been no hesitation in including the more common abnormalities when present. In certain regions plates illustrative of the different stages of dissection have been introduced. Sufficient detail has been incorporated in the text to avoid reference to books of descriptive anatomy. Amongst regions of which a particularly full description is given may be mentioned the axilla, the bend of the elbow, the palm of the hand, the gluteal region, Scarpa's triangle, the sole of the foot, and the knee-joint. The volume reflects great credit upon both the author and the artist. The descriptions given in the text are lucid and exhaustive and many little points about the illustrations bear out the author's statement that they are drawn from actual preparations. We know of no text-book which gives better or more faithful representations of the anatomy of the limbs. A student who has conscientiously followed this book in dissection cannot fail to attain an excellent and correct knowledge of the structure of the limbs. At the same time we are inclined to think that the size of the volume will to some degree militate against its use in the dissecting room, for it is much larger than the ordinary manuals used by students, and in spite of this only contains the anatomy of the upper and lower extremities. Dr. Dujarier is a pupil of Farabœuf and in the preface he pays a touching tribute to his old master by whose permission he has reproduced the illustrations of the transverse sections of the limbs.

LIBRARY TABLE.

Landmarks and Surface Markings of the Human Body. By LOUIS BATHE RAWLING, M.B., B.C. Cantab., F.R.C.S. Eng., Senior Demonstrator of Anatomy, St. Bartholomew's Hospital; Assistant Surgeon to the German Hospital, Dalston; Hunterian Professor, Royal College of Surgeons of England. With 21 illustrations. London: H. K. Lewis. 1904. Pp. 76. Price 5*s.* net.—Mr. Rawling's small manual of surface anatomy cannot fail to recall to the reader's mind the famous "Landmarks" of Luther Holden, the subject-matter of each chapter being arranged in terse sections after the style of the older book. The idea has been to produce a handy volume of landmarks and surface markings such as may prove useful both to junior and to advanced students of medicine. The work is purely anatomical, no reference being made to operations or to pathology. Such being the scope of the book there is little room for originality in the text. There are five chapters and an appendix. The chapters are devoted respectively to the head and neck, the upper extremity, the thorax, the abdomen, and the lower extremity. The appendix, which gives the lengths of various tubes and passages and the average weight of most of the organs, is a useful novelty. The book is freely illustrated, partly by reproductions of actual photographs of the living body with the surface markings outlined in black and partly by outlines showing the surface relations of the thoracic and abdominal viscera. At the side of each paragraph is a reference to the corresponding illustration. On the whole the text appears to be trustworthy but in some places greater accuracy is to be desired; for instance, the surface markings of the lower limits of the cerebrum, of the lateral sinus, and of the upper border of the cerebellum are rather loosely given. In Fig. 18 the transverse colon appears to pass behind the duodenum. We have no doubt that the book will prove handy and useful to students.

Autobiography of Frederick James Gant, F.R.C.S., Consulting Surgeon to the Royal Free Hospital. London: Baillière, Tindall, and Cox. 1905. Pp. 200. Price 3*s.* 6*d.* net.—The public work and private matters which have served to mould the character of the writer of this autobiography are set forth in a modest and graceful way in this little volume which will cause pleasure to his old colleagues and friends. Some of the most private matters, which are too sacred for the pen of the reviewer to comment on, are treated in a way that shows how deeply they have touched the author and we could almost wish that Mr. Gant had let even the bare remembrance of them pass away into oblivion. Mr. Gant has seen and done much in his 80 years and the record of his work as author, as surgeon, and on public questions is here suitably set forth. Unquestionably many of the author's good intentions have borne fruit in good deeds. Mr. Gant has many pleasant memories to live with.

The Liverpool Medico-Chirurgical Journal. Including the Proceedings of the Liverpool Medical Institution. No. 47. January, 1905. Liverpool: Medical Institution; London: H. K. Lewis. Pp. 273. Price 3*s.* 6*d.*—This issue contains a large amount of excellent material. Among the papers are the following: 1. A Report of an Interesting Case of Operation, by Mr. R. C. Dun, for Congenital Hydronephrosis, in which the position of the abdominal tumour was unusual. 2. On Puerperal Septicæmia, with special reference to the value of antistreptococcic serum, based on an observation of 61 cases. In this paper Dr. Nathan Raw says that he has never been able to isolate pneumococci or gonococci and doubts if either will produce puerperal septicæmia. 3. On the Treatment of Severe Cases of Placenta Prævia by Bossi's Method prior to the introduction of Champetier de Ribes' bag, by Dr. H. Briggs. 4. On the Successful Treatment of Foreign Bodies which have been Swallowed by the Internal Administration of Cotton-wool, by Dr. W. Blair Bell. 5. On the Theory of Purin Formation, by Dr. W. Gordon Little. 6. On the Early Diagnosis of Consumption, by Dr. John Hay. 7. On the Education of Epileptics, by Dr. W. Alexander. There is also a report of an interesting ceremony at the eighth ordinary meeting of the Liverpool Medical Institution when the late Sir William Banks on behalf of the institution presented to the President, Dr James Barr a gold badge with a riband to be worn round the neck which had been subscribed for by the members It is intended that the badge shall be handed down to successive presidents

Studies from the Department of Pathology of the College of Physicians and Surgeons Columbia University N Y Vol IX For the collegiate year 1903-04 Reprints —These reprints of the most important studies published by the workers in this department in various journals during the year 1903-04 are brought together in this form for convenience of reference The cost of reprinting and issuing these studies is defrayed by the Alumni Association of the College of Physicians and Surgeons The volume contains the following papers 1 A Study of a Bacillus resembling the Bacillus of Shiga from a case of fatal diarrhoea in a child with remarks on the recognition of dysentery typhoid and allied bacilli, by Dr Philip Hanson Hiss and Dr F F Russell The bacillus described is closely related also to the bacillus typhosus both in agglutinating reactions and in the usually observed cultural characters but can be separated from it by the absence of mobility and by its reactions in the maltose and dextrin media employed 2 Experiments relating to the Question of Fixation of Strychnine in Animal Tissues by S J Meltzer and G Langmann 3 A *Resume* of some recent Researches relating to Cytolysis and Immunity, illustrated by Dr T Mitchell Prudden 4 A Case of Multiple Fibroma (*Fibroneuroma*) of the Nerves of the Lower Extremities with Diffuse Enlargement of the Sciatics, complicating Sarcoma and Metastases in the Lungs by Dr John H Larkin 5 6 and 7 Papers by Dr F C Wood on the Prognostic Value of the Diazo Reaction in Pulmonary Tuberculosis on a Simple and Rapid Chromatin Stain for the Malarial Parasite, and on the Mixed Tumours of the Salivary Glands (illustrated) 8 9 10 and 11 Papers by Dr Augustus Wadsworth on the Agglutination of the *Pneumococcus* with certain Normal and Immune Sera, on Experimental Studies on the Etiology of Acute Pneumonitis on a Simple Method of obtaining Blood from the Rabbit and on a Convenient Method for growing and storing Virulent Pneumococci 12 Hæmolymph Nodes by Dr Hughes Dayton 13 A Bacteriological Study of Trachoma with remarks on the Occurrence of the Influenza Group of Bacteria in Conjunctivitis by Dr Arnold Knapp 14 The Bacterial Precipitins by Dr Charles Norris 15 Hæmorrhages in the Eye present at Birth illustrated by Dr F B Coburn 16 An Adenoma of Sebaceous Glands of the Abdominal Wall illustrated by Dr W C Clarke

Manual of Hygiene for Students and Nurses By JOHN GLAISTER M D Glasg D P H Cantab, F F P S Glasg Second edition Edinburgh E and S Livingstone 1905 Pp 403 Price 6s net —This new edition has been carefully revised and some additions have been made to it to make the work more complete The author from his long experience as a teacher of hygiene and public health may fairly claim to be able to measure the needs of students and nurses in a public health manual and that his book met a want is shown by the rapidity with which it was taken up by those for whom it was written This second edition will we think maintain the popularity of the manual

JOURNALS AND MAGAZINES

The Practitioner —The February issue of this magazine opens with a communication from Sir William Broadbent based upon two cases of interlobar pneumonia which are related in detail Mr Edmund Owen contributes a useful addition to the copious literature that has recently adorned the subject of loose cartilages in the knee joint Intestinal obstruction and the cervical sympathetic are dealt with respectively by Mr T Carwardine and Dr Purves Stewart, and Mr Harvey Hilliard discusses the use of ethyl chloride by the general practitioner Dr George F Still contributes a review of recent work on children's diseases

Belfast Health Journal —Vol III of this journal commences with the number for December 1904 and an editorial address to our readers which immediately follows the title page shows that its career has been one of great prosperity The first of the original articles is a report of a Health Lecture for the People delivered in the Ulster Hall Belfast by Dr Henry O'Neill on Nov 15th In subsequent articles the food supply of the city the organisation of the markets and in particular the system of meat inspection are described at considerable length In the January number the majority of the articles refer to the feeding and the general care of children Professor G Sims Woodhead's lecture on Alcohol and Public Health, delivered in the Wellington Hall Belfast, is fully reported and there are useful accounts of municipal meetings at which public health matters were discussed The general recommendations of the journal on health questions are excellent, it presents an attractive appearance and is embellished with an immense number of portraits of "Worthy Health Pioneers" including representatives of royalty and nobility as well as many who hold prominent positions in political and municipal life

New Inventions.

THE STELLITE AIR DEODORISER

UNQUESTIONABLY an important degree of purification of the air is effected by bringing it into intimate contact with a spray of water The cleansing effect of rain or even mist or fog (when they have subsided) upon the air is well known The air again in the vicinity of disturbed water as at the sea or near water falls is proverbially sweet and fresh In these circumstances it is probable that apart from mere mechanical action water present in a myriad of minute droplets acts as an oxygen carrier it may be in fact that even peroxide of hydrogen is formed and that organic impurities in the air are destroyed by this agent This is in part the principle upon which depends the purifying action of the Stellite Air Deodoriser introduced by the Electric and Ordnance Accessories Co Limited Stellite Works Birmingham It consists of a metal case containing two revolving discs between which is an air fan By means of an electric motor the metal discs are made to revolve rapidly through a pool of water placed in a container at the bottom of the apparatus The discs rapidly whisk up a stream of water droplets At the same time the fan between the discs brings air into intimate contact with these droplets and a volume of air scrubbed clean so to speak issues from a funnel shaped outlet The effect upon the air of the room is according to our experiments decidedly satisfactory The air is freshened and gives the impression of having been cooled We have tried in particular the effect of the apparatus upon the air of a chemical laboratory dense with the fumes of chloride of ammonium The air was rapidly cleaned and reduced to a perfectly clear state and ammonium salts were found in the wash water The apparatus may be applied to the cleansing or even deodorising of the sick chamber or the hospital ward Sponges moistened with a volatile antiseptic such as thymol carbolic acid or even formaldehyde may be placed in the air inlets After a very short time on merely connecting the motor with the terminals used for an electric lamp the apartment is completely pervaded with the smell of the disinfectant that has been employed Perfumes may be used with equal effect in a similar way Primarily however, the machine is an effectual air washer and as such it may obviously have numerous hygienic applications The purifying action of a spray of water upon air is of course to some extent mechanical but it is probable also that a physical and chemical effect is produced in the direction already indicated

THE LANCET.

LONDON: SATURDAY, FEBRUARY 25, 1905.

The Financial Relations between Hospitals and Medical Schools.

IT will be in the recollection of our readers that towards the close of last year KING EDWARD'S Hospital Fund for London appointed a committee to investigate and to report upon certain questions relating to the expenditure of the twelve London hospitals having medical schools. It is scarcely necessary to trace the history of the inquiry beyond indicating that it arose out of a certain agitation against medical schools where experimental research is conducted. The violent feelings of those opposed to research led to formal declarations of a direct desire to prejudice nearly all the public appeals for charitable support made by the hospitals in question, and upon these followed acrimonious discussions which gradually centred in a protest against the diversion of funds contributed for the support of a hospital to the maintenance of a medical school. In face of this charge a committee, consisting of Sir EDWARD FRY, the Bishop of STEPNEY, and Lord WELBY, was appointed and the terms of reference are printed in another column with the resulting report. It is certain that the report will be widely read and it appears to be equally certain that it will be found both surprising and disquieting to those who have at heart the interests of the hospitals and of the medical schools of London. It will be seen that the committee took rather a wide view of the scope of inquiry and sought information outside the hospitals with medical schools. In the course of the evidence many interesting facts were brought to light but these, although they bear on medical education, are outside the main object of the inquiry. The financial relations between the schools and the hospitals and the extent of their mutual dependence formed the chief subject of dispute and of inquiry.

The difficulty of disentangling the mass of evidence must have been considerable, since the terms of reference implied complete separate existence between the hospitals and the schools. Historically this is incorrect; in certain cases it is evident that there was a gradual process of growth, the hospital being created to meet the needs of the school, or the school being constructed as part of the hospital. The lack of uniformity in the history of the development of the relations between the individual hospitals and their medical schools renders impossible the formulation of general statements and continually calls into question the objects desired at the foundations of these institutions, so that the extent to which it is feasible to consider the school buildings as separable from the hospital buildings must remain doubtful. Turning, however, to the current expenditure we find greater possibility of precision and the conclusions are not creditable to our wealthy metropolis. It is lamentable that the claims of medical education should be so far ignored that it should ever be necessary for any contributions, direct or indirect, to be made to the schools out of the funds of the hospitals. There are only two institutions, King's College Hospital and University College Hospital, of which the committee is able to report that no money, given or subscribed, is contributed for the maintenence of medical education. Some doubt is expressed with regard to Guy's Hospital and the Royal Free Hospital but all the other medical schools appear to have received aid from their hospital funds. In fairness it might have been indicated that the two hospitals thus highly commended are the only two in which the medical schools form part of general teaching institutions, in every sense separate from the hospitals. In King's College and University College endless confusion would have been created by any overlapping of accounts and in both instances the hospitals were to a very large extent developed to afford facilities for clinical teaching of students trained in the parent institution. Supported primarily by the friends of these institutions it was in each case essential that the hospital funds should be distinct, since the welfare of the Colleges could not be imperilled by the uncertainty of the adequacy of charitable contributions.

The extent of benefit derived by the hospitals from their assoication with the medical schools is a matter upon which opinions may differ. It is perhaps inevitable that a committee without opportunities of personal observation should think that "the quiet of a hospital without students" must often be a comfort to patients. Much depends upon the class of students and the class of patients and the amount to which the students, as distinguished from the junior staff, are brought into connexion with the patients is less, we think, than the authors of the report imagine. It is difficult also to realise what is meant by the suggestion that "in cases of great obscurity and difficulty the presence of a large number of students may at times be useful." We believe that in cases of "great obscurity and difficulty" unofficial visits to the wards are frequently made in order that the members of the staff may form an opinion at their leisure without the disturbing need of explaining and demonstrating each step of investigation to a large class of students anxious to move on to something definite. If the large class could be composed of qualified men much help might be derived from their presence, but students demand instruction and rarely offer illuminating suggestions. Still, this portion of the report must not be criticised too rigorously, since the main facts are clearly recognised, and these are that opportunities of teaching in a hospital connected with a school will insure the gratuitous services of the most eminent men in the profession and that publicity inevitably tends to maintain the whole work at a high level. There is no need to doubt the conclusion that both the schools and the hospitals benefit from their association and that the mutual benefits may be fairly set off the one against the other.

The third point of reference, and the stern brevity of the report upon it, may lead to very grave modifications of existing conditions. The committee was asked whether there are any special considerations advanced in justification of contributions from the hospitals to the medical *schools* or any general considerations which would apply to all hospitals having medical schools. The reply is an uncompromising negative. It is, however, easy to point to circumstances showing that in some directions the medical school makes to the hospital a large return for benefits received. For example, the school supplies to the hospital a number of unsalaried officers whose places must be filled under any distinct pecuniary scheme by paid men. Evidence of this kind was placed before the committee but does not appear to have weighed with them. Much was said about the difficulties and the expenses of the medical schools and many spoke of the possibility of meeting these expenses by a judicious concentration of studies. We have recently referred to the steps which have been taken by King's College and University College to facilitate this course and in their evidence Sir ARTHUR W. RÜCKER and Mr. H. T. BUTLIN dwelt on the advantages of centralisation. The committee reports that it feels the cogency of the arguments in favour of making a broad line of distinction between the preliminary and intermediate studies on the one hand and the final studies on the other, and it refers sympathetically to efforts in this direction to free some of the schools from burthens which they find it difficult to bear. But this does not alter its view that moneys intended for the hospitals should not go to the schools. It is possible that this report may, for a time, check the flow of charitable contributions to KING EDWARD'S Hospital Fund but its general effect should ultimately be for the good of all concerned. The public have been furnished with additional proof that the hospitals are really in want of assistance, while the urgent need of reorganisation of medical education in London could not have been placed before them more forcibly.

The Influence of Diet on the Growth and the Functions of Tissues.

THE great importance of the study of the principles of dietetics and the adjustment of dietaries to the needs of the organism in health and in disease was early recognised both by physiologists and clinicians. The scientific study of the problems of metabolism constitutes a branch of physiological inquiry of which the literature is now enormous. Much of our information we owe to the work of LIEBIG, PETTENKOFER, VOIT, VON RANKE, and MOLESCHOTT and to the very valuable and ingenious researches of LAWES and GILBERT which are all of them now classical. But most of these researches have been made on chemical or chemico-physical lines and comprise among other things the construction of balance-sheets of anabolic and katabolic changes in the body and the adjustment of diet scales to varying conditions of the organism as regards age, climate, and the amount of muscular work performed. A further advance was made when by calorimetric methods of investigation the energy values of food substances were investigated by RUBNER and other physiologists so that the physiological heat value of the various articles of diet being known a diet could be constructed adjusted to the needs of the body as regards heat and the energy of muscular movement. The question of diet in disease has also received attention from the earliest times of medicine and at the present day its importance is becoming more and more recognised; and although there is still abundant scope for research on scientific lines to confirm or to modify the results of the old or empiric methods of constructing dietaries adapted to various diseases yet undoubted progress has been made.

In striking contrast to the amount of attention which has been given to these aspects of the study of dietetics is the meagreness of our information of the effects of varying diets on the histological structure and the growth of tissues and organs. The effects of various diets on the deposition of glycogen in the liver and other tissues and of fat droplets in connective tissue cells and on the growth of bone furnish perhaps the chief examples. At the same time the subject is one of undoubted importance, as we may learn from the profound alterations in the growth of bone in cases of rickets and the very extensive pathological changes in cases of scurvy due to errors of diet. The beneficial effects of the correction of such errors in these diseases are too well known to require more than passing reference. Again, the effects of some special constituents of articles of diet in producing leucocytosis afford another example of the direct effect of diet on the activities of the tissues. In this connexion a paper, published in THE LANCET of Feb. 11th (p. 347), by Dr. D. CHALMERS WATSON of Edinburgh on the Rôle of an Excessive Meat Diet in the Induction of Gout contains an account of some observations of considerable interest. In the course of a research on the pathogenesis of gout Dr. CHALMERS WATSON fed various animals upon a diet of raw meat and water, approximating to the so-called Salisbury diet sometimes prescribed for the human subject. He found that in three healthy fowls fed on such a diet for periods varying from 13 to 16 months there were striking changes in the thyroid and parathyroid glands. The thyroid showed in each case great enlargement of its vesicles and an increase in the amount of colloid material and in some instances proliferation and shedding of the glandular epithelium—in other words, changes similar to those of parenchymatous goitre in the human subject. The enlargement was of such a degree that the thyroid weighed from eight to ten times the normal amount. The parathyroids were also increased in size from microscopic structures to masses larger than a pea, which presented the appearances characteristic of normal parathyroid tissue. Similar investigations were made with rats which were also fed on a diet of raw meat and water for periods varying from six weeks to four and a half months. In ten cases out of 12 definite changes in the thyroid were found, although differing in character and degree from those observed in the fowl. Proliferation of the epithelial cells of the vesicles and of the connective tissue occurred with a diminution in the amount of colloid which showed evidence of degeneration into a mucinoid material. The appearances are stated to resemble closely those seen in cases of exophthalmic goitre in man. The parathyroids were in most cases normal.

It is to be regretted that so few details are given in Dr. CHALMERS WATSON'S paper, which is, we presume, of the nature of a preliminary communication, since we learn from him that he has other evidence as yet unpublished of similar effects in a second generation of animals as well as in the first and that he contemplates a systematic investigation of the whole question with the aid of a number of co-workers at Edinburgh. So far as his researches have gone, he is encouraged to expect valuable information on the influence of diet on the histology of the blood, bone marrow, bone, and other tissues and incidentally of its effects on catarrhal and other pathological processes. Without details of the number of animals employed in these experiments, of the number of control observations made on healthy animals of the same species under ordinary diet, and of the histological methods adopted in the fixing and preparation of his specimens it is difficult to appraise the value of Dr. Chalmers Watson's observations on the thyroid and parathyroid bodies. Again, no details are given of the relative weights of the glands in the normal rat and the rat on the raw-meat diet and, while stating that the histological appearances in the latter case were strikingly like those of the thyroid in exophthalmic goitre, he does not mention whether the proliferated epithelium approximated in type to that of the parathyroid, as is stated to be the case in that disease. With Dr. Chalmers Watson's views as to the infective nature of gout or the rôle played by an excessive meat diet in its pathogenesis we are not now concerned. He himself admits that it may be some time before conclusive evidence of an infective element is forthcoming. In this we may agree with him and regard his premiss as not proven. The feature of his work, which seems to us to be of great importance, is the evidence that different diets may be associated with demonstrable histological changes in various organs and alterations of their functional activity. The extended research which he proposes on these lines, if properly controlled by observations on normal animals and carefully carried out by various histological methods, should afford very valuable additions to our knowledge of diet in health and disease and we shall await with interest the results obtained by Dr. Chalmers Watson and his co-workers

◆

The History of the Discovery of the Acarus of Scabies.

It cannot but be instructive to review now and again the course of discovery in medicine, for by such an examination of the past we may be enabled to recognise fallacies current at the present time and may thus to some extent avoid falling into errors like those which have proved disastrous to our predecessors. Not only do we find that in former times many erroneous opinions have been held, for this is only what we expect in a science at first purely empirical, but we also find that in some cases the true theory, the correct explanation of facts, though known, has for one reason or another been discarded in favour of some utterly false hypothesis. It would not be difficult to find many examples of this but one lies ready to our hand. In the issue of The Lancet of Jan. 7th, p. 49, under the heading of "Looking Back" we reprinted a note on the etiology of scabies which had appeared in The Lancet of Jan. 6th, 1827. At that time the evidence against the parasitic origin of scabies appeared to be very strong—in fact, strong enough to overthrow completely the idea that the acarus scabiei was the cause of the disease, and the very existence of this animalcule was firmly denied. The history of this controversy from the beginning is of great interest as showing how the truth may appear, may become more or less established, and then may disappear again to await re-discovery.

The ancients confused many different diseases under the terms scabies and psora and therefore but little reliance can be placed on their descriptions. Aristotle certainly speaks of an "ἀκαρές" residing in the skins of animals but it is by no means certain that he refers to the sarcoptes hominis. It is very doubtful whether the Romans were acquainted with the presence of an insect in scabies, for most of the references which have been advanced as referring to this animal probably relate to pediculi. Abu Merwan ibn Zohr, the Arabian physician who lived in the twelfth century and is better known as Avenzoar, was the first to give such an account of the acarus as to enable us to be sure that he knew of its existence. He says, according to the Latin translation, "sunt pedicelli subter manuum, crurum et pedum cutem serpentes et pustulas ibidem excitantes aqua plenas; tam parva animalcula quam vix visu discerni valeant." It can hardly be that this description refers to pediculi corporis as Hebra has suggested; it seems clear that in this we have a description of acari living in the skin. Benedictus in 1535 gives a very similar account. Scaliger, in a letter to Cardanus in 1557, says that the acarus lives in burrows which it makes in the skin and that it is globular in form and extremely minute. Moufet, an Englishman, however, gives a very full account in his work "Theatrum Insectorum," which was published in 1634 after his death. He points out that the "animalculum est omnium minutissimum," and that the acarus "extractus acu et super ungue positus, movet se, si solis etiam calore adjuvetur." Hauptmann in 1654 was the first to print a drawing of the acarus, though it was not very accurate. Many other writers described it in the seventeenth and eighteenth centuries and among them may specially be mentioned Bonomo, Bonanni, and Baker, but the most valuable work on this subject in the eighteenth century was a book on the "Aetiologie der Kraetze" by Wichmann, published in 1786. Wichmann was the first to point out clearly that the acari live on the side of the vesicles and not in the vesicles or pustules, as was maintained by most of the writers preceding him and many of those who wrote after him. Adams in 1805 figured the acarus and described the method of extracting it from its burrow but he was inclined to think that the disease in which the acarus could be found was not identical with true scabies. Thus the matter rested until in 1812 the Academy of Sciences of Paris doubting the exactitude of the description of the acarus and its location offered a prize for a full demonstration of the situation and mode of discovery of the animal. Galès, who was an apothecary at the Saint Louis Hospital, gained the prize by a public demonstration of the extraction of an acarus from a pustule, and for a time this demonstration was held to have proved conclusively that the acarus was the cause of the disease, but doubts soon began to arise for many dermatologists examined the vesicles and pustules in cases of scabies and were unable to discover the presence of any acari. Alibert, Biett, Mouronval, and Rayer of Paris sought in vain for the animalcule and even the employment of microscopes did not enable them to find any trace of it and so disbelief in the existence of the acarus became almost universal and the passage to which we have referred as appearing in *The Lancet in 1827 was written at a time when this scepticism prevailed.*

Yet a very little attention devoted to earlier accounts of the site of the acarus would have sufficed to dispel the erroneous notions then prevalent. Moufet in 1634 had pointed out that the acarus was not *in* the vesicles or pustules but at the side. Casal of Madrid in 1762 had well described the burrows made by the acarus and Adams in 1807 had clearly said that in looking for the acarus we must not examine the vesicle but the extremity of the little line or ridge running off from it. However, Renucci of Corsica was a medical student in Paris and he had seen the people of his native country extract the organism; he was therefore able to demonstrate conclusively the presence of the acarus and to instruct others how to remove it from its burrow. Raspail investigated the subject and he showed that the illustrations of the acari "discovered" by Galès exactly resembled the "mites" of flour and were very different from the true acarus of scabies; it has, therefore, been concluded that Galès acted fraudulently in order to obtain the prize offered by the Academy of Sciences. It is conjectured that he concealed the flour mite beneath his nail and when he opened the pustule in a patient affected with scabies he brought out the mite from under his nail and presented it to the admiring spectators as the *vera causa* of scabies. There seems to be little doubt that Galès had deceived those who witnessed the demonstration. It is curious to note that many of the older observers speak of finding the acarus in the vesicle just as Galès did, though now we know that the acari never occur in the vesicles. It is a little difficult to account satisfactorily for these older accounts of the existence of the acari in the vesicles but it is probably only an error of description. When Renucci had shown how very easy it was to find the acarus when it was searched for in the right place the rôle of the acarus as the *causa causans* of scabies was fully admitted though there have been a few who have looked upon the animalcule as a result of the morbid process of scabies and not as its cause. Albin Gras published in 1834 an account of a series of experiments which he had made with praiseworthy devotion to the cause of science. He placed acari on his forearm and covered them with a watch-glass and they formed burrows. He placed others on his finger and covered them with a finger-stall and in several other ways he proved satisfactorily that the acari could give rise to the disease. We may take it that it has been proved definitely that the acarus is the essential cause of scabies and that the doubts raised by the inability to discover the acarus were ill-founded and were dependent chiefly on fraud. Though there is much excuse for the scepticism shown, yet the fact *remains that the true theory of the etiology of scabies* which had been held for several hundreds of years at least was given up in favour of an erroneous doctrine. This is by no means a solitary example of scepticism in relation to scientific discoveries. Many dermatologists may remember that Sir Erasmus Wilson would not admit the parasitic nature of ringworm and looked upon the spores in the hair as the result of a granular degeneration.

Annotations.

"Ne quid nimis."

WHAT IS PORT?

The fact that such questions are so constantly brought into public prominence as what is port, what is flannel, what is butter—instances could be multiplied *ad nauseam*—is an eloquent indication of the extent to which substitution, adulteration, or misbranding is practised. There are those who seek to convince us that old definitions are passing away. That view is at any rate convenient to those who hold a brief for the substituted article or who are interested in pushing its sale. It will not appeal, we should hope, to an enlightened public. Even the "man in the street" is too well-informed to believe that it matters little what spirit he chooses to drink because all are alcohol, which is equivalent to saying that the distinctive terms whisky, rum, and brandy are obsolete and mean nothing. We commend the admirable judgment delivered on Feb 15th by Mr. Mahony in the Dublin police courts in a case in which certain wine and spirit merchants were charged with selling a bottle of wine which was falsely labelled as port and contained Tarragona, a cheap wine not produced in, or shipped from, Portugal. The defendants contended that they had simply followed the trade custom of selling such wine as port, without any qualifying words. "Geographical words," said Mr. Mahony, "when used to designate trade products gave rise in course of time to some difficulty, as, for instance, Brussels carpets" (and he might have added Bath buns). "But," he went on to say, "there was a difference between manufactured articles like those mentioned and a natural product. The latter may, and probably does, owe its qualities to the characteristics of the real soil and the climate where it is produced. It is not likely that these peculiar local circumstances would be reproduced elsewhere and consequently the production of that particular product must be limited to its original district." He very appropriately quoted Tennyson in the following verse:—

"[illegible]

You set before chance comers,
But sack, whose father, grape, grew fat
On Lusitanian summers."

We may add that similarly the "father" of brandy should be the grape; of whisky, barley malt; of rum, sugar; and so forth. Mr. Mahony came to the conclusion that the term port applied to wine and used without any qualifying or explanatory words was only applicable to wines produced in Portugal and in the Douro district and when applied to any other wine was a false trade description within the meaning of the Merchandise Marks Act and he therefore convicted the defendants on the summons.

THE ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

At the meeting of this society on Tuesday next, when Sir *Frederick Treves will open the discussion* on the Subsequent Course and Later History of Cases of Appendicitis after Operation, records and statistics of cases, printed for the occasion, will be provided for the use of those present at the meeting. These records and tables have been collected and arranged by the surgical registrars and other gentlemen connected with some of the chief hospitals of London. Between 2000 and 3000 cases, by much work, have been thus tabulated and the conclusions to be drawn from them will add greatly to the interest and the value of the discussion. It is expected that after Sir Frederick Treves and Sir William Broadbent, the speakers will be Mr. Charters J. Symonds, Sir Lauder Brunton, Mr. A. Pearce Gould, and Sir William Bennett, and that the debate will then be adjourned to Tuesday, March 7th. This adjourned meeting will probably be held at 5 o'clock (tea and coffee at 4.45) instead of the usual hour of the society's meetings. The annual general meeting of the society, at which the President will deliver an address, will be held on Wednesday, March 1st, at 5 P.M. It is hoped that the meeting may be well attended in view of important matters to be considered.

CURRENT THEORIES OF THE HEREDITARY PROCESS.

THE fourth lecture[1] delivered by Professor W. F. R. Weldon, F.R.S., at University College, London, on Dec. 13th, 1904, dealt with the environment and its special action on developing organisms. The relation of organism to environment is a matter of common knowledge but the investigation of the special action of elements of the environment on development is a recent achievement in biology. Thus, the sea-water in which the sea-urchin lives and develops has an average composition of sodium chloride, 25·9 grammes; potassium chloride, 3·6 grammes; magnesium sulphate, 1·6 grammes; calcium sulphate, 1·2 grammes; potassium sulphate, 0·8 gramme; calcium carbonate, 0·1 gramme; and magnesium bromide, 0·1 gramme per litre. Herbst studied the development of the egg of echinus in sea-water in which one or another of these saline constituents was changed and found that, excluding the bromide, all the other salts influenced development, abnormalities being produced if these were not in the right proportions. Thus, excess of potassium chloride causes feebleness and high mortality of the embryos, while absence of calcium or the presence of small quantities of strontium or lithium produces malformed and abnormal larvæ. Fertilisation is impossible except in a slightly alkaline sea-water; in neutral or faintly acid water it does not occur. In sea-water without sulphates eggs of echinus segment normally to blastulæ and mesenchyme is formed but the latter forms a disordered mass of cells and spicules. Moreover the gut does not differentiate into three parts as it normally would and the larva remains a symmetrical gastrula with a single equatorial ciliated band and centrally situated mouth. The normal form is an asymmetrical gastrula which develops a ventral mouth, bilateral symmetry, and a complex set of three ciliated bands. Other monstrous forms of gastrulæ also occur in the absence of sulphates. If the water is warmer than the normal environment should be the endoderm cells which are formed do not invaginate to form the gut but evaginate (are everted) forming a small tubular projection which is soon thrown off from the globular blastula. Mesenchyme and spicules are formed but owing to loss of the gut the blastula is unable to feed itself and dies. Changes in temperature produce abnormalities in development as marked as changes in the chemical composition of the water. The presence of lithium salts in sea-water affects the egg as a "toxin." Thus, 1 part of lithium bromide in 1000 parts of water causes in echinus the production of an enormous everted globular gut (hyperplasia of endoderm), while the smaller ectodermal portion develops a transverse ciliated band. The character of echinoderm larvæ, says Professor Weldon, depends not only on the intrinsic quality and structure of the egg and the relations between the early blastomeres but also upon the relations between cells at various later stages of embryonic development, and all agencies in the environment, physical and chemical, such as disturb the processes of normal development show their special action at particular "critical" periods of the process. Normally and fully developed blastulæ transferred to lithium water change but little, whereas at an earlier stage the toxic and deformative effect of the lithium is shown at its maximum. Passing on to the variations of colour in insects, Professor Weldon said that they offered the most striking example of susceptibility to variation at special periods: thus, by placing caterpillars in boxes of black, golden, silvery, or other colours there were produced dark pupæ and golden-coloured pupæ (young butterflies) in course of time. Heat accelerated the formation of the pupa but did not disturb much the colouration. The characteristic change produced by heat was that the relative growth of the various parts was so disturbed that the "hot-house" pupa had the look and characters of a different species. Larva and pupa differed in their respective reactions in these respects. Every phase of development of an embryo was influenced by thermal, physical, chemical or toxic, and nutritive agencies, and no distinction could thus be made between blastogenic or somatogenic characters. No character could be shown in an animal to be completely germinal in origin and independent of environment, and the environment (and its elements) affected even closely allied animals very differently. Striking changes of colour could be produced in siren, a tailed amphibian, by exposure to coloured lights, and the absence of the stimulus of light for long periods of time produced loss of pigment as well as atrophy of the visual organs, as in the blind fauna of the Kentucky caves. The eggs of proteus (a cave amphibian of Austria) grown and hatched in light give rise to coloured larvæ unlike the normal colourless ones. The lower side of the sole which is white develops colour if the fish is reared in an aquarium the floor of which is illuminated with coloured lights from below.

THE AMETHYST-TINTED WINDOW.

IN not a few shops in London, and particularly those which have a southern or sunny aspect, there may be noticed panes of glass in the window of a violet tint. They are perhaps more frequently seen in the shop windows of silversmiths, in which the panes of glass are relatively small. We were under the impression that these panes of glass were intentionally tinted in order to lend an antique lustre to the silver goods exhibited in the window, but it appears that the colour is really due to the effect of prolonged sunlight upon the manganese in the glass. Radium will produce the same colouration in glass containing manganese and presumably the colourless manganous salt present is oxidised under the influence of sun or radium radiations. Manganese is added to glass in order to neutralise the green effect produced by the presence of iron. Amethyst-tinted windows are observed more often in silversmiths' shops, probably because many of these shops are very old and the glass panes have consequently been exposed for a long time to the action of the sun's rays. Old glass windows are generally broken up into small squares but not all the squares assume the amethyst tint, as some are probably free from manganese. According to Sir William Crookes the colouration is not superficial. It occurs intensely in pieces of glass exposed to sunlight at high altitudes, ranging from deep violet (almost black in some places) to pale amethyst. Sir William Crookes adds that sunlight and radium both produce similar effects. Their modes of action, however, are known to be in the main very different Still, it has been clearly shown that what radium is capable of doing in the way of inducing chemical change sunlight will also effect It may be noted also that the same amethyst colouration appears in some x ray tubes after constant use

[1] Abstracts of the first, second, and third lectures were published in THE LANCET of Jan. 7th (p. 42) and 21st (p. 181) and Feb. 4th (p. 307), 1905.

THE LANCET SPECIAL ANALYTICAL COMMISSION ON BRANDY

COPIES of the report of THE LANCET Special Analytical Commission on Brandy, which was published in THE LANCET of Nov 29th 1902 have been in such request as to have exhausted not only our stock of that number of the journal but of the reprints that were issued This demand has been occasioned by the successful proceedings which have been established throughout the country against vendors for selling as brandy a spirituous liquid which proved to be not of the nature substance and quality of brandy accepting that word to mean a spirit obtained by the simple distillation of grape wine The question is still occupying considerable public attention and it has been stated that the possibility of strengthening the provisions of the Sale of Food and Drugs Act so that the sale of spirits may be brought under more efficient and satisfactory means of control, is being officially contemplated In these circumstances and in view also of the fact that inquiries for more copies of the report continue to reach us we have issued a further number of reprints in pamphlet form [1] The report deals with the production of brandy at Cognac the position of the industry in the Charentes, and the supply of genuine brandy to this country

STRIÆ PATELLARES

IN the *British Journal of Dermatology* for February Dr J L Bunch has recorded two cases of the rare condition termed "striæ patellares" In the first case the patient was a boy, aged 13½ years He had typhoid fever five months previously Convalescence was slow and he was still weak and poorly nourished Above both knees were several irregular pinkish transverse striæ which appeared during the illness They varied in width from a few lines to about one eighth of an inch and tapered off somewhat at the ends During the illness he had suffered considerably from pain in the region of the knees Since the onset he had grown one and a quarter inches In the second case the patient was a girl aged 12 years, who had suffered four months previously from pleurisy and endocarditis During the illness she was kept recumbent and striæ patellares appeared but their advent was not accompanied by pain They were pinkish blue and similar to those in the preceding case A limited number of cases of striæ patellares has been recorded principally in children after typhoid fever Sir Dyce Duckworth observed unilateral striæ on the thigh after typhoid fever in a patient aged 15 years Several explanations of these striæ have been given It has been urged that unusual growth takes place in the long bones especially in the femora, owing either to absence of pressure on the epiphyses during the prolonged rest in bed or to juxta epiphyseal osteitis Measurements of the limb before and after the attack may show an increase of from one centimetre to one and a half centimetres It has also been alleged that the striæ are due to rupture of the subcutaneous tissue as a result of tension on the skin in the position in which the child lies with the legs drawn up They are not peculiar to typhoid fever, though they have been observed after this disease most frequently They have been described by Fussat and Brissaud in pulmonary tuberculosis and by Chevallereau in a patient, aged 20 years who was laid up for eight months with colitis Striæ in other positions are well recognised The best known are the lineæ albicantes of pregnancy Striæ may be produced by distension from other causes such as ascites or obesity Kirstein and Gilbert have described them on the chest in pulmonary diseases In the museum of the Hôpital Saint Louis are several models of linear striæ, in one they are the result of typhoid fever but occur on the flank Striæ are usually pink at first and after a time become white On microscopic examination of a stria which was losing its pigment Dr Bunch found changes chiefly in the elastic fibres and to a less extent in the white fibres The latter showed general thinning and a few had ruptured The interlacing of the network of elastic fibres was much less marked than normal owing to a new parallel arrangement of the fibres which had been produced at the expense of the transverse elastic fibres The latter were ruptured and retracted to the edge of the lesion where their broken ends were seen These changes were best marked in the pars reticularis of the corium

THE AFTER-CARE ASSOCIATION

ALTHOUGH the methods of treating the insane have made great strides of late there is still no provision, except that of the After care Association, for looking after poor persons discharged as recovered from asylums for the insane As a consequence many who might otherwise have a chance of becoming useful members of society relapse into their former condition This fact, we think, is somewhat of a reproach to a civilised country The association receives the small sum of £700 a year only in contributions, yet there are 7000 persons discharged annually from the asylums in this country Many of these people are friendless and without assistance find almost insurmountable difficulties in getting employment The association endeavours to facilitate the readmission of these poor people into social life by obtaining for them an interval of change of scene and air, by boarding them out in the country under proper care and supervision, by giving them grants of money, and in other ways By these methods an amount of good is done which cannot be easily estimated Certainly many people are prevented from drifting into the asylum again and possibly the procreation of mental weaklings is often hindered by the judicious care which the association exercises over its protégés We therefore cordially endorse the council s appeal for subscriptions The secretary is Mr H T Roxby, Church House Dean's yard Westminster, London, S W

UNGUENTUM ACIDI CARBOLICI

THE periodical revisions of the Pharmacopœia are necessary not only for the introduction of new remedies but also for the improvement and better description of old and well tried drugs and galenical preparations Ointment of carbolic acid has always been a difficult subject for the prescriber and the dispenser owing to the carbolic acid crystal ising out The official formula contains 1 of phenol in 25 and has for a basis a mixture of hard and soft paraffins with some glycerine The tendency to separate is overcome by adopting a slight modification of the official formula, as suggested by Morley Taylor phenol, 1 part, hard paraffin, 6 parts, and soft paraffin, 18 parts Undoubtedly this formula is superior to the official one and is to be recommended especially for obstetric use and in all cases where absorption by the skin is not desired But the desirability may be suggested of inserting in the Pharmacopœia alternative formulæ replacing the paraffin basis in this and other ointments by vegetable or animal fats or oils—e g, olive oil, lard, and wool fat—in cases where absorption is required The bases used for making ointments have been classed by Hallberg into (1) non absorbed protective, epidermatic bases—e.g., hard and soft paraffin; (2) emollient, absorbent, endermatic bases, as lard and olive oil; and (3) systematic, absorptive, diadermatic bases, as represented by wool-fat. Of the official ointments those of carbolic, boric, and salicylic acids are probably designed to afford in most cases an antiseptic protective coating. But in other cases—for example, the ointments of lead subacetate and ammoniated mercury—it is difficult to account for the choice of a paraffin basis except on pharmaceutical grounds. In devising formulæ the first consideration should be to determine the therapeutic requirements and afterwards to find out the best means of compounding the ingredients. Of the official ointments the following are also prepared with a paraffin basis though it might be expected that a more absorbent basis would be selected—ointments of yellow and red mercuric oxide, lead acetate, lead carbonate, lead iodide, and zinc oleate.

BOMBS.

WHEN left alone to its natural functions nitrogen pursues a perfectly peaceful course but when man succeeds in capturing it and combining it with other elements it becomes a dire potentiality for evil, as is obvious in the recent events of the war in the Far East and in the crime committed last week in the streets of Moscow. The love of freedom, so to speak, characteristic of nitrogen is terribly exemplified in the explosion of the bomb in which it is imprisoned and bound to other elements. On the slightest provocation—a spark, a shock, a fuse—the nitrogen suddenly expands from seemingly nothing, as regards the space which it occupies, into infinity. This is, in reality, what happens when dynamite, lyddite, or other unstable nitro-compounds explode when hurled in shells in warfare and in bombs in desperate attacks on human lives. Nitrogen, against its natural disposition, is locked up in an uncongenial space in these compounds, from which it is set free by very simple means in an enormously expanded gaseous state with deadly effect, returning, in fact, to its normal peaceful mission once more. It is the analogue of the sword and the ploughshare; in the nitro-explosive nitrogen is the modern engine of warfare and crime; in the free state in the atmosphere it ministers directly to the quiet and peaceful needs of plant and human life.

THE INCIPIENT STAGE OF INSANITY.

AMONG the many problems connected with psychology one of the most important is the early recognition of symptoms of mental aberration. It must also be kept in mind that certificates given in cases of this description have sometimes proved fruitful sources of anxiety to the medical men concerned. In a recently published pamphlet[1] Mr Charles Williams of Liverpool emphasises the great practical value of the early recognition of insanity from the point of view of treatment and prevention of family trouble, suicide, and homicide. He follows up his exhortation by stating and explaining the signs and symptoms by which incipient insanity may be detected. We imagine that all medical men are well aware of the importance of the early detection of disease whether so-called mental or physical, and in these days we should suppose that most are well acquainted with the early symptoms of insanity as described in the various text-books. But a short essay of this kind may well serve a useful purpose by supplying the intelligent public in a succinct and easily assimilable form with information which they would otherwise be not very likely to acquire. From his concluding remarks Mr. Williams evidently thinks that he may be charged with undue optimism and therefore the less compunction need be felt in ascribing this fault to him. He has a strong conviction that the early recognition of the approach of insanity would prevent large numbers of people annually from becoming insane. Mr. Williams is presumably prepared to give reasons for the belief which is in him. If medical men in general practice and the alienists whom they call in will come forward with evidence of the prevention of threatening insanity their experiences will be received with much interest by those working in the department of mental disorders. The claim to prevention must in the nature of things be eminently difficult to maintain. Mr. Williams also dwells upon the "supreme importance of eradicating, or at least attempting to eradicate, a delusion at its first inception." He says that a delusion at this stage may often be successfully removed but he does not give any instance of the operation, nor does he describe the *modus operandi*. Is it by appeal to the mind or to the body, by argument, entreaty, cajolery, or by antiphlogistics, hypnotics, and purgatives? All this is very sanguine but is it scientific? We think that even an intelligent general public may regard with scepticism these *ex cathedrâ* utterances. Mr. Williams says that from hallucinations alone a person should never be pronounced insane and asserts, apparently in all seriousness, that this view is "opposed to that generally accepted by the medical profession, the legal profession, and the public generally." Being, however, satisfied that he is correct on this point he proceeds, in this instance at any rate, to give reasons for his view. Various explanations have been put forward to account for the increase of insanity of late years, but if it were generally believed that hallucinations constituted insanity, and this belief were acted upon, an explanation for the increase would be forthcoming which we do not remember to have met with and, fortunately, have no expectation of meeting with.

THE DISSEMINATION OF PLAGUE.

AT a recent meeting of the Bombay Natural History Society an interesting paper was read by Captain W. G. Liston, I.M.S., on Plague, Rats, and Fleas. The fact that rats may play an important rôle in the dissemination of plague is now a generally accepted fact. The manner in which the disease is so spread is still under discussion and Captain Liston's views on the subject are certainly worthy of consideration. He points out that there are two species of domestic rats—the *mus decumanus*, the common rat found in Europe, a burrowing rodent living in drains and cellars, and the *mus rattus*, the common rat of Bombay and the East generally, living in the roofs of houses and even in trees. Captain Liston maintains that plague may rage as an epizootic among rats of the first-named species without human beings running much risk of being infected but that an epidemic of the disease among rats of the species *mus rattus* is very liable to be communicated to man. He further makes the interesting statement that the disappearance of plague from Europe was coincident with the invasion of that continent by the brown rat and the displacement of the black rat. A habit of rats which has an important bearing on the spread of plague is that of migrating as a community when scared by an unusual mortality among them. In these circumstances the disease would be communicated to other colonies of rats in the same town and so a fresh focus of infection might be established. Captain Liston then proceeds to consider how the disease is communicated from rats to man and points out the manner in which fleas may act as transmitters. The rat flea is seldom found on man but when the rats migrate in the presence of an unusual mortality among them some of the fleas remain behind and from sheer hunger attack man and other animals He records proof of this fact in the case of a certain epidemic among guinea pigs in an outbreak of plague in a chawl in India While normally rat fleas are never found on guinea pigs in the above instance 18 were captured on one sick guinea pig Man seldom harbours the rat flea, yet Captain Liston states that in this epidemic of 30 fleas caught on man no less than 14 were rat fleas He concludes by saying that he believes it is impossible to place a distance between rats and man except by years of sanitary improvement and education The only method that holds out any hope of success now and until sanitary reforms are carried out is to acquire immunity to plague by inoculation

THE AUTO-INOCULABILITY OF SYPHILITIC CHANCRES

IT is generally held that the pure syphilitic chancre is not auto inoculable But from the evidence brought forward by M Queyrat at the meeting of the Société Médicale des Hopitaux of Paris on Dec 23rd 1904 it would seem that this view must be modified As long ago as 1884 Pontopiddan reported at the International Congress of Medicine held at Copenhagen in that year a case of auto inoculation of a recent syphilitic chancre in three places No change was noticed until the twelfth day when red spots of the size of the head of a pin appeared On the nineteenth day they had become red papules of the size of a grain of millet On the twenty sixth day these were of the size of a pea and transformed into pustules covered with crusts and the secondary eruption appeared On the thirty second day they reached their acme On the thirty sixth day the crusts fell off and the papules *were flattening down They then gradually disappeared* Mercurial treatment was begun on the twenty sixth day Inoculation was attempted again on the twenty eighth day without success The objection was made to this experiment that the lesions produced were secondary ones Metchnikoff performed experiments which support the view that auto inoculation is possible He inoculated an orang outang with syphilis on Oct 26th and again on Nov 5th 1904 On Nov 21st a primary lesion appeared on the site of the first inoculation after an incubation period of 26 days After an incubation period of 20 days a primary lesion followed the second inoculation M Queyrat has previously recorded a case in which a man developed 11 chancres in succession of which the later ones were abortive[1] They were evidently inoculated during intercourse on successive days with the same woman This case led M Queyrat to the conclusion that immunity to syphilis is developed only gradually after the appearance of the first chancre and that therefore auto inoculation is possible At the meeting he brought forward still more cogent evidence of this view With their consent he inoculated from their own chancres three men who had contracted syphilis In all 13 inoculations were performed from chancres varying in duration from four to 28 days In each case he obtained one successful result from chancres of five five and six days duration respectively The following is an example A man aged 29 years had gone to hospital on Nov 5th with a typical syphilitic chancre on the prepuce of five days duration On the 6th (the sixth day) he was inoculated in two places in the right deltoid region with a vaccination style charged with the juice of the chancre In order to meet the objection that the result might be due merely to the injury he was similarly pricked with a sterile vaccination style in the left deltoid region in two places to a greater depth than that of the inoculations On the 18th he left hospital without having shown any signs of reaction at the inoculated spots He returned on Dec 10th with two dark red papules of the size of small lentils on the sites of inoculation and two enlarged glands in the right axilla On the left side he showed nothing He had been instructed to watch the inoculated spots and said that the papules appeared 21 days after the inoculation On the trunk was a macular secondary eruption which began eight days after the appearance of the papules of inoculation On Dec 13th the papules were surrounded with a whitish scale. After the 15th they retrogressed and the infiltration diminished On the 23rd there were only dark red lenticular macules at this time the chancre on the prepuce was completely healed. The patient was treated by injections of grey oil In the other cases the result was similar but the incubation period was only 12 days and enlarged glands were not observed The results cannot be explained by saying that they were due to auto inoculation of soft chancres, for the primary lesions had all the characters of pure syphilitic chancres and the diagnosis was confirmed by the secondary eruption Moreover the auto inoculation of soft chancres would have produced in four days pustules which would have been followed by ulceration Nor can the results be explained by the accidental inoculation of staphylococci or streptococci for the incubation period was too long and there were no signs of suppuration M Queyrat regards the lesions produced as abortive chancres produced in a 'soil on the way to immunisation They may be compared with the abortive vesicles produced when a person is vaccinated day by day

HIGH POWER MICROSCOPY

THE evening lecture at the Royal Institution on Feb 17th was delivered by Mr J W Gordon who took for his subject High Power Microscopy In referring to method of illumination Mr Gordon made special mention of the method devised by Dr Siedentopf This is a variety of dark ground illumination with cross lighting and was described in THE LANCET of July 16th 1903 p 116 Mr Gordon then went on to say that with the compound microscope when objectives of very short focal length were employed and eye piece enlargement of high magnifying power it was practicable to get a magnification of, say 2000 diameters But in these circumstances the emergent pencil of light was extremely small a state of things which involved serious practical inconveniences so that the average scale of good critical work hitherto had ranged at about from 400 to 600 diameters Mr Gordon then proceeded to describe his own method of using a ground glass oscillating screen placed in the tube at the point where the image was formed This screen broke up the small pencil of light and passed it on as a broad pencil the image carried by which could be magnified by a second microscope instead of the usual eye piece so that enormous magnifications giving a clear image, could be obtained The screen had to be kept in motion It will be remembered that this method was exhibited by Mr Gordon at the Royal Society s conversazione which was held in June 1904 when a phagocyte which had ingested tubercle bacilli was beautifully shown

CONVALESCENT HOMES ASSOCIATION

A CONFERENCE will be held in the rooms of the Royal Medical and Chirurgical Society 20 Hanover square London W on March 2nd at 4 P M of delegates from all the chief convalescent institutions which supply charitable relief to London patients The object of the conference is to obtain some form of union and cooperation between the various convalescent homes by forming a central association which will be in *immediate touch with* the hospitals on the one hand and with the various homes on the other. The following convalescent homes have decided to send representatives—viz., the Metropolitan Convalescent Institution; Mrs. Gladstone's Free Convalescent Home for the Poor, Woodford; Surrey Convalescent Home, Seaford; *All Saints' Convalescent Home*, Eastbourne; and probably St. Andrew's Convalescent Home, Folkestone. The Presidents of the Royal Colleges of Physicians of London and Surgeons of England and of the Hospitals Association and the Dean of the Faculty of Medicine of the University of London have signified their intention to be present if possible, and King Edward's Hospital Fund for London, the Metropolitan Hospital Sunday Fund, and the Metropolitan Hospital Saturday Fund intend to send delegates. It is expected also that leading medical representatives from the chief London hospitals, members of the medical profession, and leading laymen specially interested in this work will be present. Communications on the subject should be addressed to Mr. Alex. Hayes, secretary, Metropolitan Convalescent Institution, 32, Sackville-street, W., or to Dr. S. H. Habershon, 88, Harley-street, W.

---

[1] THE LANCET Sept 10th 1904 p 779

THE medical officer of health of the Cape Colony states that for the week ending Jan. 28th the condition of the Colony as regards plague was the following. At Port Elizabeth 1 case of plague was discovered during the week, namely, a native female on Jan. 25th. Of 146 rats and 182 mice examined during the same period 1 rat and 4 mice proved to be plague-infected. At East London no case of plague in human beings was discovered but 7 rats and 1 cat were found to be infected. In other districts no case of plague was discovered. As regards the Mauritius, a telegram from the Governor, received at the Colonial Office on Feb. 17th, states that for the week ending Feb. 16th there were 6 cases of plague and 5 deaths from the disease.

AS stated in THE LANCET last week the dinner in honour of the celebration of the hundredth anniversary of the birth of Señor Manuel Garcia will take place on March 17th, at 7.30 P.M., at the Hotel Cecil. Members of the profession who have subscribed to his portrait, painted by Mr. John Sargent, R.A., and who wish to attend the dinner are requested to communicate with Mr. Philip de Santi, 15, Stratford-place, London, W., one of the honorary secretaries of the Garcia committee, who has been intrusted with the arrangements for the dinner. The banquet will be attended by ladies and it is desirable that applicants for tickets should state the numbers which they require and whether they will be accompanied by ladies.

THE anniversary dinner of the Medical Society of London will be held at the Whitehall Rooms of the Hôtel Métropole on Wednesday, March 15th, at 7.30 P.M. Communications with regard to the dinner should be addressed to the honorary secretaries at 11, Chandos-street, W.

THE EPIDEMIC OF TYPHOID FEVER AT LINCOLN.

THE epidemic of typhoid fever at Lincoln appears to show at last some signs of abating but the signs are too slight to have any significance. The city has been sorely stricken and the inhabitants at the present moment are living not only in great discomfort but in considerable danger. The epidemic, excluding a few scattered cases, may be said to date from the third week in January and by Feb. 1st 268 cases had been notified. Additional cases were then notified daily, so that by the end of the first week in February over 500 cases were known to have occurred in the district, the official city total being 477. A fund was immediately opened for a supply of comforts for the patients. At the corporation offices gifts were received of clothing, bedding, and nightshirts, and a subcommittee of the health committee arranged for daily meetings. A systematic arrangement for nursing was placed under experienced control, while the local staff of nurses was largely augmented by nurses imported from other towns. Auxiliary hospitals had to be provided and at the same time the corporation issued instructions to the public with regard to the boiling of water and milk and the disinfection of sinks and drains. The big employers of labour in Lincoln coöperated splendidly with the efforts of the medical men. As well as subscribing largely to the various funds to secure nursing and adequate sick supplies they provided the families of their sick employés with free meals, and in other cases fed the men so as to lessen the risk for them of meals at their homes. In every way, in short, the city showed disposition to help the sufferers and to coöperate with the medical officer of health and the other medical practitioners of the town and neighbourhood in their earnest endeavours to stay the plague. The second week in February showed some abatement, the total for the week ending Feb. 13th being 154 cases, that for the first week of February being 268, while the shortage of pure water—for it speedily became obvious that the water-supply was at the bottom of the mischief—began to be counteracted to some extent by the carriage of water from neighbouring and presumably healthy sources. The whole story of the epidemic appears to be simplicity itself. None of the sanitary problems which often occur in connexion with sudden and severe outbursts of typhoid fever in urban communities are here present. The water-supply of Lincoln, which has for at least 20 years been known to be open to contamination, has at last been seriously poisoned. As far back as April 1st, 1885, the medical officer of health of the city, Dr. C. Harrison, presented a lengthy report on the water-supply of the city, showing that the river Witham, which is the chief source of supply, was dangerously open to outside contamination. Seven years later the Local Government Board expressed regret at learning that the corporation of the city had not decided to provide the town with a supply of water from an uncontaminated source. Between and since those dates the water-supply of the city has been amply discussed, sources of small contamination have been discovered and dealt with, and at last, five years ago, the council approved a plan of boring for water and three years ago boring proceedings commenced. In February, 1903, after one year's boring the boring tool was lost and the work has since been suspended and now the city is in a parlous state, having two needs to consider—what shall be done in the present emergency and what shall be done in the future?

As regards the present position the community is to be congratulated upon the courage and resource with which it has faced the situation. The sewage effluent from Bracebridge Asylum has been turned into the proper place for it—namely, the sewers—so that one obvious source of evil has been removed. The water supplied by the corporation, which must be drawn from the Witham, the corporation having no other source whence to procure it, is being treated with sodium or calcium hypochlorite in pursuance of an edict issued by the authority on Feb 9th. The corporation further recommends that the water should be boiled for ten minutes as an additional precaution. Various complaints have been received that the use of chemicals has given rise to colic, but not much stress must be laid upon the statement of a rightly aggrieved and naturally apprehensive public. Newark water is being supplied free of cost, by the generosity of a citizen of Newark, to the lower part of Lincoln daily and the upper part of the city is being supplied by the relief committee with water from Wilton. But much remains to be done. The total number of cases, now over 650, will certainly increase. There were nine fresh cases notified on Tuesday, Feb. 21st, and ten on Wednesday, so that the signs of abatement are, as we have said, slight. Between 650 and 700 cases of typhoid fever call for much hospital accommodation as well as much medical attention and nursing, and the provision that has so far been made with bravery and promptitude will not suffice. These are the problems of this grave emergency, but it is evident that the whole question of the water-supply of the city must be tackled in the immediate future, and the authorities, we understand, are convinced that this is so and are already consulting the engineer who was responsible for the water-supply of Manchester from Thirlmere as to the course to be taken.

MEDICINE, ITS PRACTICE AND ITS PUBLIC RELATIONS

CHAPTER II[1]

THE CONSTITUTION AND SCOPE OF THE GENERAL MEDICAL COUNCIL

The Medical Profession and General Scientific Progress —The Struggle for Registration —The Medical Act of 1858 — The Powers of the General Medical Council

THE state of the medical profession in Great Britain and Ireland is at present healthy There are many drawbacks to the medical calling to which attention must be directed at more or less length , there are many places in which reform is needed and a few in which it is urgently needed , but it is unfortunate that some in the ranks of medicine who are most earnest in their desire for the well being of their fellows should be unceasing in representing their profession as having fallen away in recent years from some higher estate This is not the case The story of the medical profession in England, Ireland, and Scotland alike is one of progress During the last 50 years the art of medicine has been entirely revolutionised, every change in it being towards a transformation into an exact science Our fields of knowledge have broadened with our capacity to till them our tools have become more delicate and more precise, and the advances made in many of the provinces of exact learning other than medical have had an influence that cannot be over estimated upon medical views Consequently the scientific equipment of the medical man of to-day differs in countless respects from that of his grandfather

The expansion of knowledge that has taken place in medicine has been going on in all other branches of knowledge, whether nearly allied to medicine or not Where the sciences more directly ancillary to medicine are concerned the old boundaries between them and medicine have been removed No one can say exactly where chemistry stops and where physiology begins, what familiarity with electricity rightly appertains to the medical man s calling, or what knowledge of physics or of statistics should be presupposed in a medical practitioner The significance of all this is very great and is not summed up in the least by saying that the medical student has nowadays much to learn The many sided and vast developments of science have of course, changed the schemes of medical study, but they have done much more than this They have altered the status of the medical man For it has now come about that instead of occupying, as he did, one peak of a tripartite eminence wherefrom the exponents of divinity, medicine, and law— "the learned professions —were wont to survey an unlettered world, he has to submit to being classed with other practical workers who have an equal claim with him to be considered men of science In a very interesting and suggestive book Mr R Brudenell Carter[2] has called attention to this fact and considers it to show that the medical profession does not hold so good a position in the public eye as it did 50 years ago Mr Carter is qualified by exactly the right practical experience to understand what he is talking about and is gifted with the best (because the clearest) literary ability to say what he means But the situation can be read in another way With the spread of knowledge the number has increased of persons who can appreciate the enormous difficulty of medical practice These may not revere the medical calling as something too learned or too mysterious for their comprehension, but they respect it because of its scientific aims Here and there a little learning may betray a man into a shallow criticism which considerably greater—or considerably smaller—information would have saved him from making, but this is a thing which will occur less and less frequently The growing public acquaintance with scientific methods must lead to an improved estimate of medicine as long as medicine progresses And medicine, being inextricably bound up with the ancillary sciences, must progress with them The medical profession has nothing to fear from a more enlightened public, on the contrary, the better acquainted the public become with the teachings of science the more certain are those who follow the calling of medicine to find many and powerful sympathisers

Fifty years ago the medical profession was divided into two classes the consultants—i e , the consulting physician and the operating surgeon—and the general practitioners The division was more marked in England than it was in Scotland and Ireland and had been much stricter in the Regency and the following decades inasmuch as the immediate effect of the passing of the Apothecaries Act in 1815 was to create an inferior order of general practitioners Thackeray with his wonderful accuracy when drawing social types has revealed the situation in one sentence the opening sentence of the second chapter of ' Pendennis "

> Early in the Regency of George the Magnificent there lived in a small town in the heart of England called Clavering a gentleman whose name was Pendennis There [illegible]
> having seen his name upon a bo
> pestle and mortar over the door
> city of Bath whence Mr Pen
> [illegible]
> farmer's
> der and

Old Pendennis was the typical product of the Apothecaries Act and in his person the general practitioner cannot be said to have enjoyed any high social or scientific status It is not meant to imply that old Pendennis was a fair example of the general practitioner up to the modern constitution of the medical profession by the passage of the first Medical Act in 1858 On the contrary for 30 years before the passage of that Act the general practitioners, most of them holding diplomas from a Royal College and some being graduates of a University, had steadily improved their position and won their way to demanding the stability and official recognition which could only be insured by passing a measure of registration It is unnecessary to write at length of the constitutional history of medicine in this country before the passing of the Act of 1858, which by creating the General Medical Council and giving to that body certain disciplinary powers revolutionised the position of affairs entirely The story of the struggles which led to the passing of that Act will be found set out from different points of view in the Carmichael Essays of the late Mr Walter Rivington and Dr E D Mapother, in the late Mr Fernandez Clarke s autobiographical reminiscences and very fully in the columns of THE LANCET It will be sufficient here to indicate the headings of an interesting story In 1827 Mr Henry Warburton, the Member for Bridport, a merchant and a business like man who later made his mark in six consecutive Parliaments as a Free trader presented a petition from the Royal College of Surgeons of England for an inquiry by the House into the management of that wealthy and influential corporation The request of the College was acceded to but no practical reform followed A *fracas* in the College building led to the formation by Thomas Wakley, then editing THE LANCET, and some of his colleagues of an abortive scheme known as the London College of Medicine The scheme was a failure from the beginning, but it contained in it two great ideas—the idea of one central governing body for the medical profession and of one entrance into the medical profession for all candidates The London School of Medicine, instituted to meet the wants of the rank and file of the medical profession who were sorely oppressed by the presence of quacks within their body and by the competition of quacks without, contained the germ of the first Medical Act, while it made the medical profession consider how necessary a central governing body must be to regularise the proceedings of medical education. The possibility of Parliamentary interference began to be apparent to all, Members of Parliament in various constituencies were asked to familiarise themselves with the idea, and in 1839 a Bill was introduced by Mr. Warburton which nearly succeeded in passing the House and which provided for the registration of medical practitioners. At this juncture Richard Carmichael, founder of the Carmichael Essays, President for the third time of the Royal College of Surgeons in Ireland and one of the most practical medical reformers of the day, wrote to Sir Robert Peel urging the necessity of registration and pointing out that uniformity of examination was also required so that the public might feel certain that by whatever portal a man entered the medical profession he could not obtain ingress without a certain equipment. Sir Robert Peel became interested in not allowing a great measure of domestic reform to be shelved and in 1840 a Bill providing for the registration of medical men was introduced by Warburton and Wakley, then a Member of Parliament, but the measure met with no success. It contained a suggestion that registered practitioners should take out an annual licence, a clause which was ill-received by medical men, although, as we know now, the merits of this reform were at least as obvious as its defects. In 1847 Wakley again obtained leave to bring in a measure entitled "A Bill for the Registration of Qualified Medical Practitioners and for Amending the Law relating to the Practice of Medicine in Great Britain and Ireland." This Bill, though it never became law, led to the appointment of a select committee of sound, shrewd, important men, whose deliberations resulted, though not immediately, in the Medical Act of 1858. Macaulay was the first chairman of the committee and representative members of all the qualifying bodies were examined at great length, with the result that in 1849 Mr. Rutherfurd, the Lord Advocate of Scotland, stated in the House that a measure providing for the registration of qualified practitioners in medicine would be laid on the table in a few days. It was found, however, that the various qualifying bodies from different motives of self-interest could not agree to support the Bill. One wanted one thing and one wanted another, and in face of the manifold opposition all attempt at legislation was again dropped. This want of ability in the qualifying bodies to combine for the common good was very mortifying to the medical reformers, and ten years elapsed before another serious attempt was made to pass a measure which all now admitted was wanted in the public behalf. In 1856, however, the Royal Colleges of England, Ireland, and Scotland, and the Faculty of Glasgow had a conference of representatives with the result that these important corporations came to an agreement as to their requirements. This appearance of unanimity led to early results, for in 1858 Mr. William Cowper introduced and secured the passage of the first Medical Act, the Act which, with its various amending measures, controls the medical profession at this day.

[1] Chapter I was published in THE LANCET of Feb 18th 1905 p 447

[2] Doctors and their Work By R Brudenell Carter, F R C S London Smith Elder, and Co 1904

The Act, which is entitled "An Act to Regulate the Qualifications of Practitioners in Medicine and Surgery," states in the first clause, as the reason for its existence, that "it is expedient that persons requiring medical aid should be enabled to distinguish qualified from unqualified practitioners." The measure was clearly designed to protect the public, any benefit that might accrue from it to the medical profession being of secondary importance. The General Medical Council was called into being by the Act which settled that certain universities and bodies should be entitled to grant medical qualifications and that representatives of those bodies, together with six nominees of the Crown, should form a central authority for the education of the medical student and the maintaining the official roll of the profession. The constitution of the Council has since been altered in two respects, notably by an amending Act in 1886. Additions have been made to the number of recognised qualifying institutions, while the members of the medical profession have been allowed to elect five of their number as Direct Representatives, three for England and one each for Scotland and Ireland. To appraise the scope of the Council's work is practically to define what has been done by the Medical Acts. The Council, then, is authorised to keep a medical register, intended to enable the public to distinguish qualified from unqualified practitioners and containing the names of all persons who are legally qualified medical practitioners and who, by virtue of their registration, are entitled to recover their professional charges in a court of law, to give valid medical certificates, to appear as medical witnesses, and to hold various offices or appointments. The Council cannot prevent the public inviting medical aid from persons not on the Register. Nor can the Council take any proceedings against such persons so long as they do not infringe the Act by pretending to be on the Register. The Council keeps the official roll of the profession but has no discretion with regard to registration. The Registrar is bound to insert the name of all applicants who are provided with the degrees, diplomas, or licences specified in the Medical Acts. The Council is authorised to remove from the Register, and thus to deprive of the above-mentioned legal privileges as practitioners, any persons who are convicted of crime or misdemeanour, or who may be adjudged by the Council itself, after due inquiry, to have been guilty of "infamous conduct in any professional respect." The clause of the Act under which its penal powers are exercised runs:—

> If any registered medical practitioners shall be convicted in England or Ireland of any felony or misdemeanour or in Scotland of any crime or offence or shall after due inquiry be judged by the General Council to have been guilty of infamous conduct in any professional respect the General Council may, if they see fit, direct the Registrar to erase the name of such medical practitioners from the Register.

It will be seen that there is no attempt at defining what constitutes "infamous conduct in a professional respect," and one of the most delicate and responsible of the Council's duties is to decide upon the justice of removing offending persons from the Medical Register. The Council is authorised to require from any of the licensing bodies information with regard to the courses of study and examinations to be gone through in order to obtain their respective registrable qualifications and to visit and to inspect the examinations. In the event of the Council considering the courses of study and the examinations insufficient to guarantee the possession by the persons obtaining the qualifications of due knowledge and skill for the efficient practice of their profession the Council can represent the fact to the Privy Council, the department of State to which it owes allegiance. The Privy Council can take such action as may be necessary. To the General Medical Council, also, is given the duty of preparing and publishing the British Pharmacopœia.

The powers of the Council as the controlling medium of the conduct of medical practitioners are elastic, but the reason of the phraseology of the Act becomes apparent when we remember that the Council exists for the protection of the public and not for the protection of the medical profession. The legislature evidently contemplated the possibility of conduct on the part of a medical practitioner which, while it might be insufficient to bring him within the grasp of the criminal law, would be amply sufficient to show his unfitness to be trusted with professional opportunities and responsibilities. The Council is intrusted with the power of deciding upon the professional behaviour of a medical man and is empowered to erase the name of anyone from the Register who does not behave in a manner befitting his delicate position towards the public. But the effect of removing a medical man from the Register is, of course, to deprive him absolutely of any legalised medical status and of any power of legally earning his living as a medical practitioner. In the case of the criminal this is not of great matter, for it is difficult to conceive any circumstances in which the medical profession and the public alike would not be benefited by the removal of a convict from the official roll, but in the case of the man whose offence is rather a proof of bad taste or bad form than of wickedness the Council shrinks from taking the extreme step of erasure in any but very gross cases. This was particularly the case when erasure from the Register was permanent, as it was in the first instance, and the terrible nature of the punishment now and again led the Council to err on the side of leniency, but an ingenious procedure, suggested to the Council by its solicitors, gave power of restoration to the Register, so that the punishment of an offender can now be made more nearly to fit the crime.

Such, briefly, are the powers and duties of the General Medical Council and for practical purposes to understand what the Council can do and cannot do is to understand the position of the practitioner under the Medical Acts. In describing the state of the medical profession in England, Scotland, and Ireland in the subsequent chapters the various obstacles that beset the path of the practitioner will be detailed. It will be found frequently that although his grievance may be acute the Council is unable to help him owing to the limitations of its powers and the very definite object of its creation—viz., the public weal. But this is not at all generally understood. What is the commonest form that the letters to the medical or lay press of the aggrieved member of the medical profession take? Surely it is to ask "Why does not the General Medical Council put down quackery?" or "Why does not the General Medical Council prevent the holder of a bogus American degree from practising?" The Council does not do these things because it has not the power under the Act and the amendments thereof to which it owes its constitution. The Council can only interfere when the quack pretends to be a properly registered person. Then under the clause of the Act which says that the Register is to be compiled for the instruction of the public, so that the public may be able to discriminate between the properly qualified medical man and the quack, the Council can take legal proceedings. It must be clearly stated that the Council, as at present constituted, cannot defend either the public or the medical profession in the way that it is often invited to do. The remedy for this ineffectiveness is amendment of the Acts.

(To be continued.)

MEDICINE AND THE LAW.

A Mysterious Case.

AT Gravesend recently an inquest which lasted for four hours elicited some curious facts relating to the death of a married woman named Cohen which are stated below in outline without comment. The deceased apparently kept a shop without the assistance of her husband who was absent during the day and who, according to his account, did not exercise any control over his wife's actions either in business or otherwise. On Jan. 13th a man came into the shop to buy a necktie and according to his account given before the coroner Mrs. Cohen, thinking that she recognised him, engaged in conversation with him and on learning that he was a medical man, a stranger to the district, said that she did not like the local medical practitioners. He subsequently had tea with her, was introduced to her husband, and on the following Sunday, Jan. 15th, came to see her again and remained as a lodger. On the Monday she consulted him about her health, when he prescribed for her, believing that she was suffering from general weakness and catarrh. She subsequently became very ill and he diagnosed pneumonia, no other medical man being called in. On the Saturday, Feb. 4th, Mrs. Cohen died and he signed a certificate as the cause of death on a form which he had had in his pocket for nine years. Examined by the coroner and in answer to questions from the jury he seems to have been unable to refer to any regular or continuous practice of recent date in which he had been engaged and he acknowledged that he had never resided at 11, Beaufort-road, Clifton, the address recorded as his in the Medical Register. His name he stated to be Arthur Piercefield Walters. Mr. P. L G Skipworth, who had made a post-mortem examination, gave evidence that the deceased had suffered from pleurisy and pericarditis but not from pneumonia. She also appeared to have had an "accident" within three weeks. The immediate cause of death, in his opinion, was heart-failure following that state which was incomplete. There was nothing to show how it had been caused. The jury, following the direction of the coroner, found a verdict that "Death was due to natural causes, in accordance with the medical evidence," and added a rider, in which the coroner concurred, to the effect that the husband had been neglectful in not calling in another medical man and that Mr. A. P. Walters had been indiscreet in residing in the house while attending on the deceased.

Looking Back.

THE LANCET, *SATURDAY*, Feb. 24, 1827.

FOREIGN DEPARTMENT.

ANATOMY AND PHYSIOLOGY.

Remarkable case of a Triple Dentition.[*]

THE following curious case has been inserted in Omodei's Journal, communicated by a Dr. Aimonino:

Elizabeth Morelli, who was a well formed woman, had enjoyed good health, and had never suffered any inconvenience, except from a few attacks of tooth-ache, for which she had been now and then bled. During one of these attacks of tooth-ache, which occurred about the middle of March in 1821, she was induced, from the severity of the pain, to have the two left molar teeth pulled out. Toward the end of October in the same year, she felt some very acute pain in the part from which the teeth had been pulled out, and soon after two new teeth made their appearance. In January 1826, the new teeth became loose, and, causing considerable pain, she had them also drawn out These teeth were very white and well shaped, without the least appearance of caries. On the 16th of July in the same year, the patient consulted Signor Aimonino, complaining of intolerable pain in the same part of the jaw as before. General and local antiphlogistic measures were tried without avail, and on the 18th, the patient perceived that two teeth of the same figure and size as the former had again made their appearance; these teeth were seen by Aimonino, so that there can be no doubt of the accuracy of the report of the case.

Although this has been called a case of triple dentition, it might with greater propriety have been called a *quadruple* dentition, since the temporary teeth are not included in the history of the case.

PATHOLOGY.

On the causes of Hernia in Soldiers.

It has been recently reported to the Academy of Medicine, that hernia has been frequently traced to the practice, existing among infantry soldiers, of firing in triple ranks. Kempfer, surgeon of a Swiss regiment of the Royal Guard, has affirmed that many cases of hernia have been produced by the sudden manner in which the privates are taught to descend on one knee after having discharged their muskets, so that their comrades in the rear may fire over their heads.

HOSPITALS AND MEDICAL SCHOOLS.

WE have received from the honorary secretaries of King Edward's Hospital Fund for London a copy of the report of the committee appointed by the Fund to inquire into the financial relations between hospitals and medical schools. The committee, it may be remembered, consisted of Sir Edward Fry, the Bishop of Stepney, and Lord Welby, and their report is as follows:—

To H.R.H. THE PRINCE OF WALES, K.G.

SIR,—1.—In October last your Royal Highness, as President of King Edward's Hospital Fund, was pleased to request us to undertake the inquiries indicated in the following terms of reference and instruction:—

"To consider and report—

1. Whether any, and if any how much, money given or subscribed for the relief of the sick poor to the 12 London hospitals having medical schools is contributed, directly or indirectly, by those hospitals, or any of them, for the maintenance of medical education.
2. Whether any direct or indirect return for such contributions (if any) is received by the hospitals from their medical schools and if so whether such return is equivalent to the amount of the contributions.
3. Whether, in the event of the committee finding that any hospital contributes to its medical school a sum in excess of the return it receives from the medical school, there are any special considerations advanced in justification of such expenditure, or any general considerations which would apply to all hospitals having medical schools.

It is an instruction to the committee to deal with the subject on [illegible] 's and to accept from the [illegible] such as they may advise [illegible] Jan. 1st, 1905."

2.—We have the honour respectfully to submit the following report *of our proceedings and of the result of our inquiries under the foregoing reference.*

3.—At our first meeting, on Nov. 4th, 1904, we settled a form of return, which we addressed to the 12 London hospitals which have schools in connexion with them. A copy of this form will be found in the first appendix to this our report.

4.—On Dec. 7th, 8th, and 10th, 1904, and Jan. 17th, 1905, we heard the oral statements of witnesses, a shorthand note of whose evidence appears in the second appendix to this our report. Furthermore, we have also met on Dec. 9th, 1904, and received and considered the replies of the 12 hospitals to the forms of return, a statement laid before us by the Hon. Stephen Coleridge, and a summary which has been prepared of the reports of the ordinary expenditure of the 16 largest London general hospitals for the year 1903.

5.—The replies of the hospitals to the forms of return have undergone a close examination and have been the subject of interviews between certain of the authorities of the hospitals and the committee and of correspondence between our honorary secretary and some of these authorities, and the original replies have in several cases been modified. The best results of this examination which we are able to supply will be found in the third appendix to this our report.

6.—We find it impossible to answer the first head of inquiry in the terms in which it is addressed to us for the following reasons:—That in the case of several of the hospitals (as St. Mary's) the hospital and school were founded together and the school as well as the hospital appears to have been an object of bounty in the minds of the founders; that in some cases (as University College Hospital) the hospital was founded as an aid to the school; that in some cases (as Charing Cross and Westminster Hospitals) the school buildings were provided or partly provided by money subscribed for the specific purpose or for a joint purpose of which the provision of school buildings formed a part; that in other cases sums have been contributed to hospitals, subsequent to the foundation, of which, to the knowledge of the donors, a portion was applied to the school, as, e.g., in the case of the London Hospital, where a contribution to the school has been made yearly under resolutions passed at meetings of the subscribers entitled to vote under the rules; and that where the hospital and school form a single conjoint institution (as in the case of the Middlesex Hospital) and contributions have been made to that institution it is obviously impossible to say how much was given for the relief of the sick poor and how much for the promotion of medical education.

7.—In our investigation of the matters arising under the first inquiry we have therefore, but of course merely for purposes of convenience, treated the question as if modified by the deletion of the words "for the relief of the sick poor" and as if all the moneys contributed to the hospitals were properly applicable to the hospital only and not to any extent to the school.

8.—But, even after eliminating this difficulty, we have found that the very intimate and complex relations which have grown up between the hospitals and the schools present insuperable difficulties to the prep[illegible] the actual cash value of the balance betw[illegible] kind made by the hospitals to the scho[illegible]ospitals; and this altogether apart from [illegible]f the work done by the schools for the [illegible]nd on which the school buildings stan[illegible]pital but the buildings have been erected by the school. In some cases parts of the buildings of the hospital are used conjointly for the purposes of hospital and school, especially in the case o[illegible]boratories, and the apportionment of [illegible] the single institution would be a [illegible]f experts. Another difficulty aris[illegible]xpenditure by the hospitals on account of the schools. In the case of St. Bartholomew's Hospital records of considerable debts, said to have been incurred by the school as far back as 1843, and still remaining undischarged, are extant, and it must be obvious that the yearly cost to the hospital of such debts, which appear to have borne no interest, could only be accurately estimated after an elaborate inquiry involving questions as to the constitution of the body it is sought to make liable and the admission of any liability by such body, if it actually exists, whether legal or otherwise. The question of the value of land is also important and can only be satisfactorily dealt with by competent surveyors, as we find that the rateable value in the case of hospitals is an untrustworthy guide, even if the school buildings were capable of being separately rated, which in some instances is scarcely the case.

9.—We have therefore thought it better to confine ourselves to statements of fact in regard to each hospital, and these will be found in the Third Appendix, which we adopt as part of our report. We believe the facts fairly cover the ground of inquiry, but the assessments of the money values which should be set against considerations which do not take the form of money payments must be left to professional valuers should it be thought desirable to further prosecute these inquiries.

10.—We have, however, no hesitation in reporting that in the cases of King's College Hospital and University College Hospital it may fairly be said that no money given or subscribed to those hospitals was in the year 1903 *(the last year for which the accounts are complete)* contributed directly or indirectly by the hospitals for the maintenance of medical education.

11.—In the cases of Guy's Hospital and the Royal Free Hospital we doubt whether, on consideration of all the circumstances (and especially in the case of Guy's Hospital to the facts stated by the Dean of the Medical School, see Appendix III.), the schools can be considered as deriving any pecuniary benefit from the hospitals.

12.—In the case of all the other hospitals—namely, Charing Cross, the London, the Middlesex, St. Bartholomew's, St. George's, St. Mary's, St. Thomas's and the Westminster, we report that, in our judgment, contributions, either direct or indirect, or both, were made in the year 1903, to the schools out of the funds of the hospitals.

13.—With reference to the first part of the second head of inquiry—viz., whether any direct or indirect return for the contributions made by the hospitals to the schools is received by the hospitals from the medical schools—we have come to the following conclusions:—

14.—(A) We find that, in some cases, the fact that a large body of students and of medical men are being, or have been, educated in a hospital, diffuses a wide interest in that institution and thus tends to aid the finances of the hospital.

15.—(B) We find that the presence of a body of eager young men watching the *proceedings of their teacher* has the tendency to keep the medical man on the alert and to counteract the effects of the daily routine of duties; and that the opportunity for teaching a large number of pupils attracts to hospitals with schools the gratuitous services of the most eminent men in the profession.

16.—(C) We think that the publicity which attends the work of a hospital where there is a body of young men in attendance also tends to maintan at a high level the whole work of the institution.

17.—(D) It has been urged before us that the great amount of work done without payment, or with inadequate payment, by students in the character of medical clerks and dressers and in connexion with the outpatients and the casualty cases constitutes a pecuniary advantage received by the hospital from the school; but the evidence satisfies us that the expenses incurred in hospitals with schools are generally in excess of those in hospitals without schools and we are of opinion that no saving of expense can be *attributed to the presence* of medical students. On the contrary, some of the evidence before us, together with a study of the accounts of the various hospitals, has brought to our attention remarkable variations in the expenses incurred by the several hospitals, and raises the important question whether, in the case of some of the hospitals to [illegible] there is not considerable [illegible]

18.—(E) With re[illegible] so largely on the ch[illegible] medical men and nurses concerned with eac[illegible] to draw any line between the two classes of hospitals. Probably, in cases of great obscurity and difficulty, the presence of a large number of students may at times be useful; but, on the other hand, we think that the quiet of a hospital without students must often be a comfort to patients and, on the whole, we do not th[illegible]h schools can substantiate any superiority in [illegible]spitals.

19.—(F) As regards the [illegible] science and the consequent benefit to the public the existence of a medical school is, in our opinion, of the highest value. [illegible] the greatest facilities of any city in the world [illegible] for surgical and medical research and we reg[illegible] importance that the greatest use should be [illegible] In making this statement, however, we feel bound to call attention to what we have said in a subsequent paragraph of our report (paragraph 25).

20.—We cannot doubt that the presence of a medical school has a tendency to give to t[illegible] hospital a progressive character as well as an [illegible] tending to the advancement of medical and [illegible] it seems to follow, as a consequence in such cases, that the real administration of the hospital will be placed mainly under the control of the medical staff and that the expenditure of the hospital will *thereby tend to increase.* On the other hand, though the absence of a school may have a *tendency* to give to the management of the hospital a stationary character and to leave the administration mainly in the hands of a lay body of managers, the evidence before us shows that some hospitals without schools are excellently conducted and can compare favourably with some hospitals with schools.

21.—By the second part of the second head of reference we are asked to ascertain in each case whether the direct and *indirect* return received by the hospital from its medical school is equivalent to the amount of the contribution made by the hospital to the school. Inasmuch as the returns, whether direct or indirect, are of a general kind and cannot be reduced to definite figures in money value, we find it impossible to give a categorical reply to this inquiry. But the general conclusion at which we have arrived is the following. The schools confer certain considerable benefits on the hospitals, and the hospitals, by opening their doors to the students, provide a clinical laboratory and allow the students of the school to work there. This confers on them a very great benefit because without the admission to the hospital the students could obtain little or no clinical teaching. These mutual benefits may, we think, be fairly set off the one against the other.

22.—If that be done, as we think it fairly may be, it follows that, in the case of the schools which last year received benefits in money or money's worth from the hospitals over and above the benefits last alluded to, there is no return made by the schools to the hospitals which can be treated as recouping this expenditure of the hospitals [illegible] ragraph 7) the the pecuniary [illegible] saying that, we do not find justification of [illegible] general con- [illegible] dical schools [illegible] red to us, but we desire to add that, [illegible] with a view to [illegible] so closely connected [illegible] to lay minds [illegible] distinction ought to be drawn between the studies of the first three years of a [illegible] the last two years—or, intermediate studies on [illegible] r, and that whilst the [illegible] age within the walls of [illegible] versity character, and, further, [illegible] hospitals to associate with themselves schools teaching the preliminary [illegible] source of the [illegible] s and the con [illegible] al [illegible] find that the [illegible] ect the Senate [illegible] secure such [illegible]

Edw Fry,
O G. Stepney,
Welby

J. Danvers Power, Hon Secretary, 8th February, 1905.

THE AUTOMOBILE EXHIBITION AT OLYMPIA.

Automobiles have never been displayed in England to better advantage than at the exhibition at Olympia at West Kensington, which came to an end on Monday evening last. The vast building is an ideal one for such a purpose, but it was none too big for the demands made upon its space. All the exhibits were excellently staged and must have been an object lesson to the uninitiated on the vast industry which has grown up more or less in our midst in the course of a very few years—an industry which is fast becoming "all British," and therefore the more pleasing viewed in the light of our so called insular prejudices

The automobiles included every form of ordinary car, from the smallest "runabout" and "buckboard" to the stately and luxurious De Dietrich 40 h.p. touring car, "fitted up as a miniature hotel, with easy chairs for the day time, beds for night travelling, and all conveniences, including cooking-stove, linen cupboard, pantry," &c, as the catalogue puts it. There were also several specimens of luxurious motor-boats, a 40-feet Napier river cruising launch, with its four cylinder ten h.p motor in a glazed case and its fittings all silver plated, well entitling it to its designation of *modèle de luxe*. A formidable-looking craft, in contrast, was the 40 feet steel torpedo boat shown by Messrs Thornycroft, with its torpedo slung over the side, carried in toggle lever jaws, and developing 108 h p with its four cylinder petrol engine

In the "heavy" or "commercial" section was to be found perhaps the greatest development of the motor industry—that development which is to revolutionise the road traffic of this and all other civilised countries. And in this connexion the excellent specimens of motor omnibuses on exhibition attracted much attention. Messrs. Thornycroft had a 36 seated double-deck petrol omnibus, the Milnes-Daimler Co. a similar vehicle and Messrs Straker and Squire one built to the order of the London Road Car Co. to carry 34 passengers. Of parcels and delivery vans, wagons, and such-like vehicles there were many on view, including a seven-ton wagon built for the War Office and a five-ton railway company's wagon. Agricultural motors by the Ivel Co, for attaching to ploughs, reapers, binders, and mowers, and for driving all kinds of farm machinery; an armoured motor, by the same company, for hauling guns into the firing lines, which is protected by a bullet proof cover, a motor lawn mower by Messrs. Ransome, and several other developments, all bore witness to the more than partial eclipse of the horse in the very near future

To turn to the class of vehicles in which the readers of The Lancet may be said to be more particularly interested, it cannot be claimed that there is any material departure from the designs of last season; rather have the makers turned their attention to perfecting those minor details which add so much to the trustworthiness of the motor-car and to the comfort of those using it A point which was particularly in evidence was the greater attention which is being paid to the coach-work and upholstering—a feature to be attributed to the fact that some of the best known carriage-building firms are now awaking to a due appreciation of the great strides being made by the motor industry, and are working accordingly

To attempt to enumerate or to describe in even the slightest detail the many hundreds of cars on view is an impossibility within the limits of space at our disposal, and therefore it must suffice to say that Humber and Co., the Siddeley Autocar Co, S F. Edge, Limited, the Duryea Co, Panhard and Levassor, E H Lancaster, C. S. Rolls and Co, De Dion Bouton, Limited, the Daimler Motor Co, Minerva Motors, Limited Sir W G Armstrong Co, Charles Jarratt and Letts, Limited, the Hozier Engineering Co, Limited, the Ariel Motor Co, the Vauxhall Ironworks Co, Limited, J E Hutton, Limited, A Darracq and Co, John Marston Limited, Orleans Motor Co., and Clement Talbot, Limited, had on view cars which especially attracted our attention, though it is quite possible—indeed, almost a certainty—that several equally meritorious vehicles of other firms escaped our attention altogether. Many, of course, were of the distinctly "luxurious" class, altogether beyond the means of the average general practitioner, but there were many at prices ranging between £300 and £500 which would be found quite suitable cars for the hard daily work required in the practice of the medical man, and which would also be calculated to give a satisfactory return for the capital invested

In the gallery were to be seen the hundred and-one details commonly termed "accessories," which may be broadly held to include everything other than the framework and body of the car, and to include also the clothing of its occupants The accessories generally do not call for any comment at present, but the question of tyres is an all-important one To the medical man especially this may be said to be the point upon which hinges his decision in the question of motor *versus* horse There is no room for doubt now that, so far as the motor itself is concerned, the experimental stage has been passed: it has become a perfectly trustworthy instrument in the hands of the man of average intelligence But no such hall-mark can be set upon the tyres. they have a far more severe duty to perform in the hands of the experienced and inexperienced alike Makers are no doubt doing their best, and that best has been successful up to a certain point; but the ideal is far from having been reached at present If the judgment of the majority is to be accepted on this point, Dunlop tyres are easily first, with Michelin and Continental following closely behind; but we are inclined to to the belief that for the medical practitioner, to whom freedom from punctures is of the utmost moment, some such tyre as that known as the Palmer cord tyre is likely to be the best investment Collier tyres, too, are worthy of note in that they are spoken of very highly on account of their non-puncturing qualities. That makers are alive to the drawbacks connected with pneumatics is patent from the efforts which are being made in connexion with solid tyres, notably so with the De Nevers grooved solid tyre, the Goodrich, the double arch, and the Sirdar buffer tyres. We do not suggest that the present-day solid tyre is suitable for the medical man who is constantly using his car; the vibration set up, especially on bad roads, would become unbearable and harmful.

To sum up the result of our observations, we are convinced that the day of the cheap and trustworthy motor is not yet, and we are prepared to proffer the opinion that it never will be. Cheapness and "reliability" in motor construction do not synchronise: the former is ever throttling the latter. No motor-car to stand constant work, the sort of work that the general practitioner would want to extract from it, can yet be put upon the market at less than from £300 to £400, though many excellent little cars suitable for occasional and week-end uses can be had for much less.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8809 births and 5189 deaths were registered during the week ending Feb. 18th. The annual rate of mortality in these towns, which had been 18·4, 18·0, and 17·4 per 1000 in the three preceding weeks, further declined to 17·3 per 1000 last week. In London the rate was 16·8 per 1000, while it averaged 17·6 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 7·1 in Aston Manor, 7·5 in King's Norton, 7·6 in Handsworth (Staffs), 8·3 in Coventry, 9·3 in Hornsey, 10·5 in Leyton, 10·8 in Smethwick, 11·0 in East Ham, and 11·2 in Walthamstow; the highest rates were 24·1 in West Hartlepool, 24·7 in Merthyr Tydfil, 25·8 in Ipswich, 25·9 in Stockton-on-Tees, 26·1 in Preston, 28·2 in Hanley, 30·5 in Portsmouth, and 35·0 in Rhondda. The 5189 deaths in these towns last week included 410 which were referred to the principal infectious diseases, against 376, 368, and 401 in the three preceding weeks; of these 410 deaths, 129 resulted from measles, 118 from whooping-cough, 67 from diphtheria, 44 from scarlet fever, 28 from diarrhœa, 22 from "fever" (principally enteric), and two from small-pox. No death was registered from any of the principal infectious diseases in Hastings, Brighton, Bournemouth, Great Yarmouth, Walsall, Handsworth (Staffs), Smethwick, Aston Manor, or Barrow-in-Furness; while they caused the highest death-rates in Portsmouth, Reading, Hanley, Nottingham, Preston, Stockton-on-Tees, South Shields, and Merthyr Tydfil. The greatest proportional mortality from measles occurred in Leyton, Portsmouth, Southampton, Reading, Nottingham, Stockton-on-Tees, Gateshead, Cardiff, and Merthyr Tydfil; from scarlet fever in Merthyr Tydfil; from diphtheria in Coventry, Salford, and Swansea; from whooping-cough in Hanley, Wigan, Preston, Halifax, Rotherham, Hull, South Shields, and Rhondda; and from diarrhœa in Bury. The mortality from "fever" showed no marked excess in any of the 76 towns. Of the two fatal cases of small-pox registered in these towns last week one belonged to London and one to Bradford. The number of small-pox patients under treatment in the Metropolitan Asylums Hospitals, which had been 15, 13, and 9 at the end of the three preceding weeks, had further declined to eight at the end of last week; three new cases were admitted during the week, against one in each of the two preceding weeks. The number of scarlet fever cases in these hospitals and in the London Fever Hospital on Saturday, Feb. 18th, was 2016, against 2096, 2070, and 2077 on the three preceding Saturdays; 241 new cases were admitted during the week, against 251, 229, and 260 in the three preceding weeks. The deaths in London referred to pneumonia and diseases of the respiratory organs, which had been 478, 444, and 400 in the three preceding weeks, further declined to 378 last week, but were 29 above the number in the corresponding period of last year. The causes of 57, or 1·1 per cent., of the deaths in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Portsmouth, Bristol, Nottingham, Cardiff, and in 47 other smaller towns; the largest proportions of uncertified deaths were registered in Liverpool, Warrington, Blackburn, Preston, Sheffield, Sunderland, South Shields, and Gateshead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 20·3, 19·9, and 18·2 per 1000 in the three preceding weeks, rose again to 18·9 per 1000 during the week ending Feb. 18th, and was 1·6 per 1000 in excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 12·8 in Leith and 16·3 in Edinburgh and in Greenock to 22·2 in Dundee and 24·4 in Perth. The 633 deaths in these towns included 25 which were referred to whooping-cough, 13 to diarrhœa, seven to "fever," four to measles, and three to diphtheria, but not any to small-pox or scarlet fever. In all, 52 deaths resulted from these principal infectious diseases last week, against 79, 85, and 49 in the three preceding weeks. These 52 deaths were equal to an annual rate of 1·6 per 1000, which was 0·2 per 1000 above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of whooping-cough, which had been 46 and 23 in the two preceding weeks, rose again last week to 25, of which 20 occurred in Glasgow and four in Edinburgh. The deaths from diarrhœa, which had been 19 and nine in the two preceding weeks, increased again to 13 last week and included six in Glasgow, three in Leith, and two in Dundee. The fatal cases of "fever," which had been six, four, and five in the three preceding weeks, further rose last week to seven, of which three cases of enteric fever were registered in Glasgow and three of typhus in Aberdeen. The deaths from measles, which had been six, six, and seven in the three preceding weeks, declined to four last week and included three in Glasgow. The deaths referred to diseases of the respiratory organs, which had been 163, 146, and 130 in the three preceding weeks, further declined last week to 119 and were 48 below the number in the corresponding period of last year. The causes of 16, or nearly 3 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 25·5, 24·2, and 25·2 per 1000 in the three preceding weeks, declined again to 23·5 per 1000 during the week ending Feb. 18th. During the past four weeks the death-rate has averaged 24·6 per 1000, the rates during the same period being 17·7 in London and 19·5 in Edinburgh. The 171 deaths of persons belonging to Dublin registered during the week under notice were 12 below the number in the preceding week and included eight which were referred to the principal infectious diseases, against 18, 9, and seven in the three preceding weeks; of these, three resulted from "fever," two from measles, one from diphtheria, one from whooping cough, and one from diarrhœa, but not any from small-pox or scarlet fever. These eight deaths were equal to an annual rate of 1·1 per 1000, the death-rates last week from the principal infectious diseases being 1·1 in London and 0·9 in Edinburgh. The fatal cases of measles, which had been 13, five, and none in the three preceding weeks, numbered two last week. The three deaths from "fever" were slightly in excess of the number in the preceding week. The 171 deaths in Dublin last week included 27 among children under one year of age and 39 among persons aged 60 years and upwards; the deaths of infants corresponded with the number in the preceding week, while those of elderly persons showed a small decline. One death from violence and six inquest cases were registered; and 64, or more than a third, of the deaths occurred in public institutions. The causes of seven, or more than 4 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet Surgeons: H. J. Haddon to the *Renown* on commissioning with nucleus crew; H. Elliott to the *Hannibal*; J. McElwee to the *Empress of India*; and F. J. Burns to the *Bacchante*. Staff Surgeon R. F. Bate to the *President* for three months' hospital course. Surgeons: F. C. B. Gittings to the *Hannibal*; M. Cameron to the *Pembroke*, lent to Chatham Hospital; T. W. Myles to the *Vivid*, lent to R.M. Infirmary, Plymouth; A. D. Spalding to the *Vernon*, additional for the *Niger*; E. Arkwright to the *Flora*; J. A. L. Campbell to the *President*, additional, for three months' hospital course; and K. H. Jones to Hong-Kong Hospital.

ROYAL ARMY MEDICAL CORPS

Lieutenant Colonel J Magill C B to be Colonel vice A H Anthonisz retired (dated Dec 22nd 1904) Lieutenant-Colonel H R Whitehead to be Colonel vice J M Beamish retired (dated Jan 26th 1905)

The undermentioned Lieutenants are confirmed in that rank —D D Paton J A Longley N E Dunkerton S C Bowle G S C Hayes C Ryley P Dwyer P C T Davy W H Hill J T C Mackenzie, H T Wilson R C *Hallowes J Campbell G A D Harvey, H O Wrackworth* H W Russell F J H Luxmoore H C Sidgwick M Sinclair, G R Painton N Low A H Fraser R H L Cordner A T Frost K A C Doig P A Jones H O M Beadnell O R Millar G H Richards and J St A Maughan

The undermentioned gentlemen to be Lieutenants on probation (dated Jan 31st 1905) —Charles Pinkerton Thomson George Wykeham Heron Robert John Bertram Buchanan George Brooke Forbes Churchill William Steward Nealor James Edward Hoar Richard Grave Meredith Frederic Emilius Roberts George Smith Wallace Wilfred Parsons Arthur Anderson McNeight Ernest Brabazon Booth Thomas Holroyd Gillen Richard James Campbell Thompson Ernest George Robert Lithgow Pierce Lower Charles William O Brien Ryder Percival Nash James Sydney Pascoe Cecil Dacre More Holbrooke John Maurice Bride Rahilly George Grant Tabuteau Richard Edmond Humfrey William George Maydon and Garfield Ormrod

The undermentioned Lieutenants are seconded under the provisions of Article 349 Royal Warrant for Pay and Promotion Oct 26th 1900 (dated Jan 31st 1905) —G W Heron J M B Rahilly and R J C Thompson

INDIAN MEDICAL SERVICE

The King has approved of the following admissions to the Indian Medical Service —To be Lieutenants (dated Sept 1st 1904) Horace Sidney Matson Donald Steel Francis Hugh Stewart Hampton Atkinson Dougan Alexander Cameron Alfred Henry Proctor Robert Tait Wells Ian Macpherson Macrae Charles Cecil Connock Shaw Roderick Dear MacGregor James Wilson Herbert Babington Alexander Spalding Mackie Peebles and Francis Broughton Shettle

The King has also approved of the retirement from the service of the undermentioned officer —Surgeon General Sir Benjamin Franklin K C I E K H P (dated Jan 1st 1905)

IMPERIAL YEOMANRY

Royal North Devon (Hussars) Surgeon Lieutenant *W F L A Holcroft is seconded for service under the* Colonial Office (dated Jan 21st 1905) Lanarkshire (Queen s Own Royal Glasgow) Surgeon Captain H Kelly to be Surgeon Major (dated Feb 18th 1905)

VOLUNTEER CORPS

Royal Garrison Artillery (Volunteers) 1st Gloucestershire Surgeon Lieutenant Colonel D S Davies resigns his commission and is granted the honorary rank of Surgeon Colonel with permission to wear the prescribed uniform (dated Jan 4th 1905)

Rifle 2nd Volunteer Battalion the King s (Liverpool Regi [illegible] G Westby (Brigade Medical Officer Liver [illegible] granted the honorary rank of Surgeon Colonel (dated Feb 18th 1905) 1st Roxburgh and Selkirk (The Border) Surgeon Lieutenant Colonel J S Muir resigns his commission and is granted the honorary rank of Surgeon Colonel, with permission to to wear the prescribed uniform (dated Feb 18th 1905) [illegible] Clark [illegible] Officer [illegible] urgeon Lieutenant Colonel (dated August 23rd 1893) 5th (Ardwick) Volunteer Battalion the Manchester Regiment Surgeon Captain S Nesfield to be Surgeon Major (dated Feb 18th 1905) 1st Sutherland (The Sutherland Highland) Surgeon Lieutenant J MacLennan resigns his commission (dated Feb 18th 1905)

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS)

The Edinburgh Company William Darling to be Lieutenant (dated Feb 18th 1905)

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS)

DISTRIBUTION OF PRIZES

On Feb 18th, at the headquarters of the Royal Army Medical Corps (Volunteers) London Companies Calthorpe street W C Mrs Keogh presented the prizes won during the year Lieutenant Colonel Valentine Matthews the commanding officer said he regretted that the strength of the companies had decreased from 380 in 1900 to 332 in 1904 The efforts made to obtain recruits had been very [illegible] d that if the authorities would [illegible] ip clause for a year or two as an [illegible] be more satisfactory In reply to a vote of thanks to Mrs Keogh proposed by Colonel J Cantlie Surgeon General A H Keogh the Director General of the Army Medical Service said that he had formed a very high opinion of the Volunteer Medical Corps in the Boer war and he knew no reason why the volunteer medical companies should not be as efficient in the field as the regulars of the Royal Army Medical Corp The duty of the medical corps was not merely to look after the sick and wounded in war but to prevent disease and to maintain the fighting strength of the army in the field In the event of any future war he would have no hesitation in calling on the Volunteer Medical Corps He would not send them out as individuals as in the last war but as a unit to be employed with the Army Medical Corps and he was sure that if he called on them they would do their work as well as those of the regular army The distribution of the prizes was followed by a dance

DEATHS IN THE SERVICES

Lieutenant Colonel *Edward Denham Tomlinson* A M D (retired) and late of the York and Lancaster Regiment on Feb 17th at Folkestone in his sixty ninth year He entered the army in 1860 as an assistant surgeon served in the New Zealand war and was present at the capture of the redoubt of Katikara and of the Pahs at Manutahi Matai tawa Te Arei and Waikoukou the action of Poutoko, the attack on Sentry Hill the ambuscades at Tapuie and Wairau and the destruction of Pahs and villages in the neighbourhood of W rea He retired in 1880

THE ARMY AND PARLIAMENT

There can be no doubt that army matters will form one of the earliest and most important subjects for the consideration of the present Parliament and there are already indications that such will be the case First and foremost Mr Arnold Forster s radical and bold army reorganisation scheme has to be put *on its trial and there are* a number of other questions connected with the defence of India and the Indian army recruiting the colonies and the newly proposed educational tests for the competitive examination of army candidates which will also surely *claim attention The position of the* medical services and the inadequacy and imperfect organisation of the means at our disposal for the relief of the sick and wounded in case of our unhappily having to take part in any big war have also to be faced and settled on some workable basis adapted to modern war methods

THE INDIAN MEDICAL SERVICE AND CIVIL EMPLOYMENT

In reply to a question by Mr *Hemphill in the House of* Commons last week Mr Brodrick stated that officers of the Indian Medical Service in civil employ in Burma were placed upon the same footing as officers in other departments in respect of local allowances in December 1903

THE WAR IN THE FAR EAST

The events which have recently been taking place in Manchuria have not so far been favourable to the Russian force The attempt to turn the Japanese left ended in failure and the latest news is to the effect that a division of the Japanese force is now in the rear of General Kuropatkin s army and threatening its communications As having some bearing upon hospital supplies it may be mentioned that a general strike has been declared at all the pharmacies in Moscow 14 of the largest pharmacies have been compelled to cease operations Among them is the celebrated Ferrein pharmacy of V K Ferrein in the Nikols kaya the largest dispensing establishment in the world There are only 50 pharmacies altogether in Moscow, the number being strictly regulated by law
